**Abstract**

Despite recent progress in defining the ciliome, the genetic basis for many cases of primary ciliary dyskinesia (PCD) remains elusive. We evaluated five children from two unrelated, consanguineous Palestinian families who had PCD with typical clinical features, reduced nasal nitric oxide concentrations, and absent dynein arms. Linkage analyses revealed a single common homozygous region on chromosome 8 and one candidate was conserved in organisms with motile cilia. Sequencing revealed a single novel mutation in LRRC6 (Leucine-rich repeat containing protein 6) that fit the model of autosomal recessive genetic transmission, leading to a change of a highly conserved amino acid from aspartic acid to histidine (Asp146His). LRRC6 was localized to the cytoplasm and was up-regulated during ciliogenesis in human airway epithelial cells in a Foxj1-dependent fashion. Nasal epithelial cells isolated from affected individuals and shRNA-mediated silencing in human airway epithelial cells, showed reduced LRRC6 expression, absent dynein arms, and slowed cilia beat frequency. Dynein arm proteins were either absent or mislocalized to the cytoplasm in airway epithelial cells from a primary ciliary dyskinesia subject. These findings suggest that LRRC6 plays a role in dynein arm assembly or trafficking and when mutated leads to primary ciliary dyskinesia with laterality defects.

**Introduction**

Motile cilia and flagella are essential, highly conserved organelles that extend from the cell to perform specialized functions, including motility and propulsion, and are present in the upper and lower respiratory tract, brain ventricles, and reproductive organs. A motile cilium is composed of an axoneme containing nine outer microtubule doublets and an inner central pair. The outer doublets are associated with dynein motor proteins, organized as outer dynein arms (ODA) and inner dynein arms (IDA). These proteins allow adjacent outer doublets to slide against one another and thus provide movement. Nexin links tether dynein arms (IDA). These proteins allow adjacent outer doublets to slide against one another and thus provide movement.

LRRC6 Causes PCD

shRNA targeted sequences generated by the Children’s Discovery Institute shRNA Library Core, were inserted into pLKO.1 lentivirus vectors that includes a U3 promoter and a puromycin resistant cassette. The shRNA sequences used were: GCCCAAGGTAGGAGAAGTAAT (shRNA#1), GAACA-CAACGACTGT GTCAT (shRNA#2), GATCTCA-GACCGGTTCATT (shRNA#3), CCTGTTTGTATTCTCCT GAAT (shRNA#4) and CCTAAATGTGAATGAGCCCAA (shRNA#5). A non-targeted sequence with a yellow fluorescent protein (YFP) reporter (a gift from Y. Feng and G.D. Longmore), was used as control [32]. Undifferentiated airway epithelial cells were transfected and selected using established protocols [33,34]. Briefly, vesicular stomatitis virus envelope glycoprotein (VSV-G)-pseudotyped vectors were generated by three-plasmid cotransfection of HEK 293T cells using Fugene 6 (Roche, WI). The generated viral supernatant was collected, filtered and used to infect airway epithelial cells. These cells were then selected by adding puromycin to the culture media. Once confluent, airway epithelial cells were grown at an air-liquid interface.

Epithelial Cell Immunofluorescent Staining and Immunoblot Analyses

Normal human lung obtained from excess tissue donated for lung transplantation was fixed, immunostained and imaged as previously described [31,35]. Human tracheobronchial epithelial cells (hTEC) collected from non-PCD subjects and differentiated at an air-liquid interface [31] were similarly examined for protein expression using primary antibodies against LRRC6 (1:100, HPA028058/SAB2103053, Sigma Aldrich, MO), acetylated α-tubulin (1:5000, clone 6-11-B1, Sigma Aldrich), LAMP2 (1:200, Abcam, Cambridge, MA), EEAL1 (1:100, BD Biosciences, San Jose, CA), γ-tubulin (1:500, Clone GtU-58, Sigma-Aldrich), DNAH7 (1:50, Novus Biologicals, Littleton, CO), and DNAH11 (1:5000, gift from Dr. Lawrence Ostrowski, University of North Carolina, Chapel Hill, NC [36]) which were detected using secondary antibodies conjugated to Alexa Fluor dyes (A-21202, A-21206, A-21208, Life Technology, Grand Island, NY). Nuclei were stained using 4′, 6-diamidino-2-phenylindole 1.5 μg/mL. Images were acquired using epifluorescent microscopy and adjusted globally using Photoshop (Adobe Systems, San Jose, CA). Cells were imaged and recorded as previously described [31,35]. For immunoblot analyses, cell supernatants were resolved by SDS-PAGE (7.5%) then transferred to PVDF membranes. The immunoblots were blocked, incubated with anti-LRRC6 (1:100 dilution, SAB1407241, Sigma-Aldrich) or anti-Foxj1 antibody (1:300), and detected with enhanced chemiluminescence using established protocols [35].

RT-PCR Analyses

RNA expression was assessed by RT-PCR amplification using the following oligonucleotide primer sets: human LRRC6, 5′-GCAGGCTTTGTGAGGTGTT and 5′-GCCGTGTAAGT-GGTCTTGTGT; murine LRRC6, 5′-AAGTTGACCACG-CAAGCAT and 5′-CTACGTGGCTACATCGCG; Foxj1, 5′-CCCCAGCAGGTGAGCTAC and 5′-GGCGGAGA GTAGAGATTG; DNAH1, 5′-AACGAGGGCTGTCCCTAAAG and 5′-GCCCTACAAAGCCGC; DNAH2, 5′-ACTGCGAAGTTGATCCT and 5′-CCTCTCCTCAGGCTC. ACTTGTG, and detected using SYBR green in Lightcycler 480 (Roche, Indianapolis, IN) [37]. Briefly, RNA was isolated from
cells using an Illustra RNAspin kit (GE Healthcare, Buckinghamshire, UK). RNA was reverse transcribed using a cDNA Reverse Transcription Kit, and then amplified using the TaqMan Fast Universal PCR Master Mix (both from Applied Biosystems, Carlsbad, CA). Gene expression was normalized to glyceraldehyde 3-phosphate dehydrogenase expression.

Airway Epithelial Cell Videomicroscopy and Electron Microscopy

Nasal epithelial cells collected from subjects with PCD were examined using previously published protocols [38]. Videomicroscopy of ciliated epithelial cells was performed using an inverted microscope with a 20X phase contrast objective (Eclipse Ti-U; Nikon, Melville, NY) enclosed in a customized environmental chamber maintained at 37°C. Images were captured by a high-speed video camera and processed with the Sisson-Ammons Video Analysis system (Ammons Engineering, Mt. Morris, MI, USA) and analyzed using established methodologies [13,39]. Cilia beat frequency was analyzed in at least five fields obtained from each cell preparation. Patient samples were prepared for electron microscopy using previously published protocols; a minimum of 10 ciliary axoneme cross-sections were reviewed and examined in a blinded fashion to define ultrastructure using established criteria [17]. For shRNA treated samples, more than 100 axonemes were blindly reviewed by investigators and scored for ultrastructural defects [13].

Statistical Analyses

Data are expressed as mean ± standard deviation (SD). Statistical comparisons between groups were made using single factor analysis of variance (ANOVA) with Bonferroni correction for multiple comparisons. Individual comparisons were made using Student Two-tail test.

Results and Discussion

Five subjects with clinical features consistent with PCD, including chronic sinusitis, bronchiectasis, recurrent otitis media and laterality defects, from two unrelated, consanguineous Palestinian families were studied (Figure 1A and Table 1). Subjects had reduced nasal nitric oxide concentrations; a finding associated with PCD and is suggested as a screening tool [38,40,41]. No ciliary motion compared to healthy controls (Supplementary video S1 and S2), and absent dynein arms (mean ODA and IDA numbers: 0.3±0.4 and 0.4±0.6 per axoneme, respectively; n = 30 axonemal cross sections) were found in at least one of the affected siblings from each family. Analysis of single-nucleotide polymorphism (SNP) haplotype on three affected members in one family (III-1, III-2 and III-4) in Figure 1A revealed multiple regions of homozygosity in each individual, but all three shared a single homozygous genomic region on chromosome 8 (125.70–142.16 Mb, based on Human Genome build 19). Shared haplotype of STR markers that span the region (D8S1720, D8S256 and D8S1743) were noted in two affected siblings from a second family (III-1 and III-4) in Figure 1B. Within this common 16.45 Mb genomic region, 43 protein coding genes were present, and seven candidates [LRRC6, KLAAT196 (MIM 610657), EIF2C2 (MIM 606229), NDRG1 (MIM 605262), EFRSA (MIM 611798), EIF2C2 (MIM 606229), and DDEF1 (MIM 605953)] were annotated in the ciliary proteome [26]. Only one gene was conserved across all organisms with motile cilia, and DNA sequencing revealed a single, novel, missense mutation that created a G-to-C change at base position c.436 (Chr8:133645203) in exon 5 of LRRC6 (leucine-rich repeat containing protein 6), which resulted in substitution of aspartic acid to histidine (Asp146His) (Figure 1C). Within this common 16.45 Mb genomic region, 43 protein coding genes were present, and seven candidates [LRRC6, KLAAT196 (MIM 610657), EIF2C2 (MIM 606229), NDRG1 (MIM 605262), EFRSA (MIM 611798), EIF2C2 (MIM 606229), and DDEF1 (MIM 605953)] were annotated in the ciliary proteome [26]. Only one gene was conserved across all organisms with motile cilia, and DNA sequencing revealed a single, novel, missense mutation that created a G-to-C change at base position c.436 (Chr8:133645203) in exon 5 of LRRC6 (leucine-rich repeat containing protein 6), which resulted in substitution of aspartic acid to histidine (Asp146His) (Figure 1C).

LRRC6 Causes PCD

LRRC6 was originally identified as LRTP and expressed during spermatogenesis in mice and humans [42]. LRRC6 contains 6 N-terminal LRR repeats, an LRRCap domain and a CS-like domain near the C-terminus [43]. The (Asp146His) falls in the LRRCap domain, a sequence important for protein-protein interaction,
regulation of RNA-binding specificity, and RNA nuclear export [44]. Expression of the C. reinhardtii orthologue was increased following deflagellation when compared to pretreatment values, consistent with transcriptional up-regulation of flagellar genes during cillogenesis [45]. The homologous gene in D. rerio (Lrrc6l), when mutated, results in ciliary motility defects ranging from immotility to disorganized beating in the pronephros and neural tube, but normal axonemal ultrastructure [27]. D. melanogaster tilB mutants have defective sperm flagella motility and dysfunctional ciliated dendrites of the chordotonal organs. Furthermore, these mutant sperm axoneme lacked dynein arms [46]. The LRRC6 orthologue, TbLRTP, of the T. brucei localizes to basal bodies and is critical for basal body duplication, flagellum assembly, and cytokinesis [47]. Altogether, these data indicate that the LRRC6 protein has conserved functions central to ciliary and flagellar processes.

To better elucidate the function of LRRC6 in cilia assembly, we examined its expression in human airway epithelial cells. LRRC6 was not found in the ciliary axoneme, but was distributed throughout the cytoplasm of ciliated airway epithelial cells (Figure 2A and 2B), and localized proximally to basal bodies (Supplementary Figure S1), suggesting its involvement in assembly or trafficking during cilia biogenesis.

LRRC6 expression was silenced using an RNAi approach in primary airway epithelial cells obtained from excess tracheal and bronchial tissue from healthy lung transplant donors to define its role in differentiation, cilia assembly, and function. LRRC6 was reproducibly inhibited by each of the LRRC6-specific shRNA sequences when compared to cells transfected with non-targeted shRNA sequences as determined using both RT-PCR and immunoblot analyses (Supplementary Figure S2A and S2B). Cilia were present on the apical surface of cells treated with shRNA sequences and affected individuals, which showed that LRRC6 was not required for ciliogenesis (Supplementary Figure S2C). When compared to non-PCD or non-targeted shRNA transfected cells (Figures 2C and 2E, respectively), LRRC6 was markedly reduced in the cytoplasm of nasal epithelial cells from PCD subjects (Figures 2D and 2F). Furthermore, consistent with the axonemal defect observed in affected subjects (Figure 2H), ultrastructural analyses of cilia from silenced airway epithelial cells had truncated or absent dynein arms (Figure 2J) compared to normal and non-targeted shRNA transfected cells (Figure 2G and 2I, respectively).
To examine the role of LRRC6 in dynein arm assembly, we immunostained ciliated cells with antibodies against DNAI1, an outer dynein arm polypeptide, and DNAH7, an inner dynein arm polypeptide. Neither DNAI1 nor DNAH7 were detected in cilia from PCD subjects, but DNAI1 was found in the apical cytoplasm of the epithelial cell (Figure 3A) suggesting mislocalization of the protein and failure of axonemal transport. In contrast, DNAH7 was not detected in the PCD cells, which may be related to protein degradation or suppressed expression. The latter was further evaluated by examining the expression of DNAI1 and DNAH7 in nasal cells for PCD subjects. DNAI1 and DNAH7 transcription was markedly reduced in nasal cells from three PCD subjects (III-1, III-2 and III-4 in Figure 1A) compared to a healthy control; findings that were also recapitulated in Lrrc6-specific shRNA targeted cells, suggesting that mutations in LRRC6 alters the expression of genes encoding some ODA and IDA proteins (Figure 4). While these findings indicate that LRRC6 is important for expression, trafficking, or assembly of normal dyneins, the pattern was also reminiscent of mislocalization of the ODA dynein DNAH5, previously described in PCD subjects with certain DNAH5 mutations [48], where mutations in DNAH5, hindered proper trafficking of ODA proteins into the ciliary axoneme and led to their accumulation in the cytoplasm. These findings further support the notion that ODA and possibly IDA proteins are assembled in the cytoplasm and are transported into the cilia axoneme as precursors. Furthermore, airway epithelial cells transfected with LRRC6-specific shRNA had markedly slower ciliary motion when compared to controls, as assessed using high-speed videomicroscopy (Figure 5). Nasal cells collected from subjects with PCD had no cilia motion when examined using high-speed videomicroscopy (Supplementary Videos S2) [38].

The relationship between LRRC6 expression and ciliogenesis, was examined using primary culture of hTEC as previously described [31]. LRRC6 was initially detected during early ciliary differentiation, which coincided with the expression of the master ciliogenesis gene, Foxj1 (Figure 6A and 6B) [31]. This relationship was further established by assessing Lrrc6 expression in airway epithelial cells isolated from syngeneic wild-type (Foxj1+/−) and Foxj1-deficient (Foxj1−/−) mice [49]. Lrrc6 levels were markedly reduced in Foxj1−/− airway epithelial cells when compared to Foxj1+/− cells (Figure 6C and 6D), indicating that Foxj1 regulated Lrrc6 expression.

In summary, we show that a mutation in LRRC6, Asp146His, caused PCD in affected individuals from two unrelated families, which resulted in axonemal defects of the dynein arms and ciliary motility. The association between LRRC6 and PCD was also recently reported in European subjects, thus confirming the importance of LRRC6 in cilia structure and function [30]. The ultrastructural and functional phenotypes observed in our cohort were recapitulated in LRRC6-silenced human airway epithelial cells. Regulated by Foxj1, LRRC6 is expressed in the cytoplasm of normal ciliated airway epithelial cells and absent from the ciliary axoneme, indicating that it is not a structural protein, findings that are consistent with published proteomic analyses that did not detect LRRC6 in cilia [51,52]. The absence of LRRC6 in cilia from these studies, and mislocalization of outer dynein, DNAI1, suggests a role in the preassembly of the dynein arms, like DNAAF1, DNAAF2, and DNAAF3, or their transport to the basal bodies, similar to ODA16 [14,20,25]. The novel finding of reduced expression of the outer and inner arm markers, DNAI1 and DNAH7, may also indicate that LRRC6 is involved in transcriptional regulation of some dynein proteins. Our findings are consistent with observations in other experimental models that...
conclusively show LRRC6 and its orthologues are involved in cilia assembly and function [50]. Thus, LRRC6 can be added to the rapidly growing list of genes that when mutated cause PCD.

Supporting Information

Figure S1 Co-localization of LRRC6 with different organelles. Immunofluorescent staining of tracheobronchial epithelial cells from healthy subject showing no co-localization of LRRC6 (red) with markers of endosomes (green), and lysosomes (green). However, LRRC6 localized with γ-tubulin, a marker for basal bodies (green). Nuclei were stained using DAPI (blue). acetylated γ-tubulin, a cilia marker, is shown in turquoise (scale bar = 10 μm).
