Realizing the Potential of Cancer Prevention — The Role of Implementation Science

Karen M. Emmons, Ph.D., and Graham A. Colditz, M.D., Dr.P.H.

In the past two decades, we and others have estimated that more than half of cancers could have been prevented by applying knowledge that we already have. Tobacco use, inactivity, and obesity are modifiable causes of cancer,1-3 and evidence now suggests that vaccination against the human papillomavirus, the use of aspirin and selective estrogen-receptor modulators, and participation in screening programs further reduce the risk of specific cancers.4,5 The effect of these strategies on cancer-related outcomes in the general population is significant. A 62% reduction in lung-cancer mortality is associated with smoking cessation at age 50,6 and environmental and policy strategies are effective at increasing cessation.6-8,26 However, the current federal excise tax on tobacco, $1.01, is low as compared with the average of about $3.15 per pack in high-income countries worldwide. There is often statistically significant variation among the states in the implementation of the evidence base. One example is state tobacco taxes, which range from 17 cents to $4.35 per pack of cigarettes.27 Raising cigarette excise taxes at the state and federal levels is viewed as a key strategy in reducing smoking prevalence, yet almost one third of states have not raised their taxes in 10 years. Long-standing gaps in access to cessation treatment were addressed in the Affordable Care Act (ACA),28,29 which is now at risk.

Similar gaps in the implementation of the evidence base can be seen in nearly all known cancer-prevention strategies. Simply put, as a nation, we continue to underinvest in primary prevention and screening and fail to adopt strategies to ensure that all population groups benefit equally from our knowledge of cancer prevention. As a result, cancer morbidity and mortality are unnecessarily high,30 and these high rates translate into huge health care costs and a devastating burden for patients and their families.31,32 Prevention is much less expensive. For example, the economic cost of smoking is estimated at $300 billion a year.33 Every $1 expended on a comprehensive smoking-cessation program in Massachusetts was associated with a return on investment of $2.12.34

The evidence on cancer prevention has not been adopted in the United States as effectively as it might have been (Table 1). Among the strategies for the prevention of cancer, smoking cessation has the longest-standing evidence base. Environmental and policy approaches (e.g., taxation and restrictive policies) that reduce the rate of risky behaviors and that increase access to treatment are particularly important for tobacco control at the population level.6,8,26 However, the current federal excise tax on tobacco, $1.01, is low as compared with the average of about $3.15 per pack in high-income countries worldwide. that we conduct more dissemination research and implementation research focused on cancer prevention. Dissemination research is the systematic study of processes and factors that lead to the widespread use of an evidence-based practice. Implementation research focuses on understanding the processes and factors that are associated with the successful integration of evidence-based practices in a particular setting (e.g., a primary care clinic or school) and on evaluating the effects of any adaptations of the practices that are needed in that setting. Together, these two approaches, supported by strong and growing methods, can help us bend the curve on the use of evidence on cancer prevention. Dissemination and implementation research focused on the strategies needed to enhance population-level cancer prevention may be particularly productive.

Environmental and policy initiatives can reach a large number of people efficiently. Dissemination and implementation research can help to elucidate organizational factors that may speed implementation differentially across settings. For example, worksite smoking bans and comprehensive smoking-cessation programs have been effective strategies for reducing smoking among adults, and the organizational characteristics associated with the adoption of smoking bans have been identified. Future opportunities for

* CDC denotes Centers for Disease Control and Prevention.
† BMI denotes body-mass index, calculated as the weight in kilograms divided by the square of the height in meters. Some organizations now classify obesity as a BMI of 30 or higher.
‡ The lack of physical activity is defined as no leisure-time physical activity among persons 18 years of age or older.
§ The percentages for colon-cancer screening are based on persons between 50 and 75 years of age for whom the screening met the recommendations of the U.S. Preventive Services Task Force.
¶ Data on mammography are from women 40 years of age or older who had a mammogram within the preceding 2 years.
‖ Data on the Papanicolaou (Pap) test are from women 21 to 65 years of age who had a Pap test within the preceding 3 years.
** These children received at least three vaccinations against the human papillomavirus (HPV).
†† Vaccinations against hepatitis B virus (HBV) were administered from birth through the age of 3 days.
policy interventions might focus on areas where there has been resistance to the adoption of evidence-based strategies, such as states with low excise taxes or limited implementation of restrictive smoking policies, as noted above. Environments that provide access to groups with an elevated prevalence of risk-related behaviors are another important target. For example, higher rates of implementation of evidence-based tobacco-control interventions are needed in settings that provide care to people with mental health and substance-abuse issues, since the prevalence of smoking in these two groups is much greater than that in the general population.\(^3\) Only 35% of substance abuse treatment facilities\(^4\) have a smoking ban, only about half provide any counseling or medication for smoking cessation,\(^5\) and psychiatrists deliver cessation counseling to patients who smoke at only 12% of visits.\(^6\) Despite the demonstrated efficacy of smoking-cessation treatment in the context of mental health care, only 13 states require provision of cessation treatment in facilities that provide treatment for alcohol abuse, drug abuse, or other conditions related to mental health.\(^7\) It is likely that the facilitators of the adoption of antismoking policies are different in treatment centers and the workplace. Dissemination and implementation research can help to determine how to increase the use of smoking bans and the provision of comprehensive treatment in these settings, as can changes in state and federal policy that provide protection from exposure to secondhand smoke and ensure access to cessation treatment.

The setting in which cancer is treated is another important target for increasing the use of evidence on cancer prevention. The 2014 Surgeon General’s report concludes that there is a causal relationship between smoking and adverse health outcomes and mortality among people with cancer and that all-cause mortality could be lowered in such people by 30 to 40% if they would stop smoking at the time of diagnosis.\(^8\) Reasoning by analogy, a cancer center that did not use evidence-based chemotherapy protocols would not be competitive for funding from the National Cancer Institute. Applying the same expectation for the evidence-based treatment of behavioral risk factors among people with known cancer could accelerate the reduction in the risk of death for the 13 million cancer survivors in the United States and thereby benefit not only patients but their families and caregivers. Dissemination and implementation research should focus on improving our understanding of the factors at the provider, patient, organizational, and policy levels that impede the adoption of evidence-based cancer-prevention strategies.

Increased population-level access to cancer prevention can also be achieved by focusing research efforts across multiple levels of influence, often through new and nontraditional partnerships. As the examples above illustrate, there is a need for both policies that encourage behaviors related to risk reduction and access to evidence-based treatments. If the ACA is largely repealed, access to evidence-based treatment will be reduced or eliminated for millions of smokers. Access to cancer-screening services will also be reduced. Other avenues of access must be created. The Center for Medicare and Medicaid Services (CMS) could use its innovation awards to aid the development of new strategies that would provide access to screening services and to expand the use of evidence-based cancer-prevention strategies, as it has done in helping to reduce the risk of cardiovascular disease. It would be valuable to determine whether state-level efforts lead to outcomes that are different from those supported by CMS investment, whether CMS resources could be used to advance state-level efforts to boost the implementation of evidence-based research, and whether partnerships with parties whose focus is not health care (e.g., schools, churches, and government agencies such as agriculture and housing) could help to increase use. In collaboration with the National Institutes of Health and the Centers for Disease Control and Prevention, targeted research opportunities could be created to maximize the knowledge gained.

Social determinants contribute to disparities in cancer morbidity and mortality.\(^9\) Organizations that serve communities with limited economic resources, such as safety-net health centers, have a particular role to play in ensuring equitable access to cancer-prevention programs. However, given limited resources and high demand, it can be difficult to integrate new practices into such organizations. Initial work suggests that some of the characteristics of an organization or community (e.g., the willingness of leaders to engage, tension with regard to change or a perception
that the current situation is intolerable, and the presence of formally appointed implementation leaders, in addition to characteristics of the intervention itself, differentiate systems that adopt evidence-based practices from lower-performing systems.\textsuperscript{44,45} Research is needed that incorporates the full range of factors that influence implementation in areas that serve populations with a high cancer burden and limited resources.\textsuperscript{46}

**CONCLUSIONS**

If we are to benefit as a nation from our investment in cancer research, it is imperative that we focus on strategies that will reduce the variation in the implementation of effective cancer-prevention programs. We have much to learn from organizations and communities that make greater use of prevention-focused policies, and we need to broaden our understanding of the social, political, and environmental factors that favor the implementation of evidence-based programs.\textsuperscript{47} If our efforts to reduce the cancer burden are to go beyond rhetoric, they must address the factors involved in implementation that account for disparities in outcome and have the greatest effect on populations with the largest cancer burden. When we implement evidence-based prevention and screening programs correctly and at scale, we achieve substantial population benefits. Although many efforts are under way to maximize our knowledge about the causes and treatments of cancer, we can achieve reductions in the cancer burden right now by doing what we already know works. Enhanced investment in research that increases our understanding of how to implement the knowledge we have is needed. Our moonshot is right here — ready for the taking.
