Global health is threatened by emerging viral infections, which largely lack effective vaccines or therapies. Targeting host pathways that are exploited by multiple viruses could offer broad-spectrum solutions. We previously reported that AAK1 and GAK, kinase regulators of the host adaptor proteins API and AP2, are essential for hepatitis C virus (HCV) infection, but the underlying mechanism and relevance to other viruses or in vivo infections remained unknown. Here, we have discovered that API and AP2 cotrafﬁck with HCV particles in live cells. Moreover, we found that multiple viruses, including dengue and Ebola, exploit AAK1 and GAK during entry and infectious virus production. In cultured cells, treatment with sunitinib and erlotinib, approved anticancer drugs that inhibit AAK1 or GAK activity, or with more selective compounds inhibited intracellular trafﬁcking of HCV and multiple unrelated RNA viruses with a high barrier to resistance. In murine models of dengue and Ebola infection, sunitinib/erlotinib combination protected against morbidity and mortality. We validated sunitinib- and erlotinib-mediated inhibition of AAK1 and GAK activity as an important mechanism of antiviral action. Additionally, we revealed potential roles for additional kinase targets. These ﬁndings advance our understanding of virus-host interactions and establish a proof of principle for a repurposed, host-targeted approach to combat emerging viruses.

Introduction

A major threat to human health is posed by emerging viruses, such as dengue (DENV) and Ebola (EBOV). Dengue is estimated to infect 390 million people annually in over 100 countries (1). Dengue fever can progress to a life-threatening disease, known as severe dengue, particularly upon a secondary infection with a heterologous DENV strain. Consequently, development of a dengue vaccine has been hampered by the necessity to generate simultaneous protective immunity against 4 distinct DENV serotypes (2). As a further challenge, recent studies have suggested that preexisting DENV immunity may enhance Zika virus (ZIKV) infection and vice versa, and consequently increase disease severity (3–5). While an Ebola vaccine could provide broad-spectrum coverage. The host-targeted approach is attractive, particularly for the treatment of emerging viral infections lacking any treatment, given the opportunities to repurpose already existing drugs that are known to modulate speciﬁc host functions with tolerable side effect and toxicity proﬁles. Intracellular membrane trafﬁc is one of many cellular processes hijacked by viruses. Membrane trafﬁc relies, in part, on the interactions between adaptor protein complexes (API through AP5) and the transmembrane cargo. The well-characterized clathrin-associated APs, API and AP2, are heterotetrameric complexes, which orchestrate the formation of vesicles destined for bidirectional transport in the secretory pathway and for endocytosis from the plasma membrane, respectively (8). The 2 host cell kinases AP2-associated protein kinase 1 (AAK1) and cyclin G–associated kinase (GAK) regulate
vivo functional relevance remain unknown. In the present study, we demonstrate a role for AAK1- and GAK-regulated AP1 activity in HCV release and document that HCV particles specifically cotraffic with AP1 and AP2 in live cells. We also show a requirement for AAK1 and GAK in the life cycles of DENV and EBOV. Furthermore, we provide support for the feasibility of repurposing sunitinib/erlotinib combination as a broad-spectrum antiviral approach using in vitro models of multiple viral infections and murine models of DENV and EBOV. Lastly, we characterize the mechanism of action of sunitinib and erlotinib by validating AAK1 and GAK as critical mediators of the antiviral effect and revealing additional potential antiviral host targets, which include AXL receptor tyrosine kinase (AXL), KIT proto-oncogene receptor tyrosine kinase (KIT), and the proto-oncogene RET.

Results
APs cotraffic with HCV and orchestrate infection. To determine the differential roles of AP1 and AP2 in HCV infection, we examined the effect of depleting their μ subunits in Huh7.5 human hepatoma

Figure 1. AP1 and AP2 cotraffic with HCV and orchestrate infection. (A) Confirmation of gene expression knockdown by Western blot in Huh7.5 cells stably expressing AP shRNA or nontargeting control (NT). (B) Entry of HCV pseudoparticles (HCVpp) was measured by luciferase assays at 48 hours after infection. (C) HCV RNA replication measured via luciferase assays 72 hours after HCV RNA electroporation. (D) HCV infectivity measured via luciferase assays by inoculation of naïve cells with lysates (intracellular) and supernatants (extracellular) from electroporated cells. (E) AP1 ectopic expression following transfection of Huh7.5 cells with Gluc-tagged WT, T144A AP1, or an empty control; blotted with anti-GLuc antibody. (F) HCV intra- and extracellular infectivity in AP1-overexpressing cells versus control. Shown are means ± SD (n = 3–10). (G) Representative live cell fluorescence microscopy montages of TC-core HCV (green) cotrafficking with AP1- and AP2-mCherry (red). Distance traveled (μm) and time elapsed (min:s) during video acquisition are indicated. (H) Quantification of motile TC-core puncta cotrafficking with AP1, AP2, and LC3. (I) Quantification of distance traveled per acquisition of WT or Y136A mutant TC-core HCV associated with AP2. (J) Quantification of distance traveled per acquisition of TC-core HCV associated with AP1 or AP2 upon treatment with sunitinib (4 μM) and erlotinib (10 μM). Results in B–D and F represent data pooled from at least 2 independent experiments each with 6–10 biological replicates. H–J are representative experiments out of at least 3 conducted. Shown are means ± SD; ***P < 0.001 relative to corresponding NT (B–D), empty vector control (F), WT TC-core (I), or vehicle control (J) by 1-way ANOVA, followed by Dunnett’s (B, D, and J) or Tukey’s (F) multiple comparisons test or 2-tailed unpaired t test (I).

RESEARCH ARTICLE

The cellular infectivity was not affected by overexpression of either WT or T144A AP1 (Figure 1F). In contrast, extracellular infectivity increased upon ectopic expression of WT AP1 and decreased with ectopic expression of T144A AP1 (Figure 1F). Thus, viral release emerges as yet another step of the HCV life cycle, beyond entry and assembly, which is regulated by AAK1 and GAK.

While APs were postulated to directly mediate intracellular viral trafficking, this has never been addressed experimentally in live cells with any virus. To test the hypothesis that HCV particles shuttle with clathrin APs intracellularly, we used live cell imaging. The cotrafficking of individual, infectious HCV particles harboring a tetracysteine (TC) tag within the core protein (TC-core) with AP1- or AP2-mCherry was monitored (32). We previously have shown that TC-core motility requires HCV virion assembly (32).
The role of AAK1 and GAK in DENV infection in cells. The requirement for AAK1 and GAK in viral infections beyond HCV is unknown. To investigate whether another, distantly related member of the Flaviviridae family relies on these regulatory kinases and their associated AP targets, we examined the effect of the corresponding gene silencing on DENV infection in human hepatoma (Huh7) cells. We observed a requirement for AP2, but not AP1, in DENV entry using cell lines stably expressing shRNA targeting AP1, AP2, or a nontargeting (NT) sequence (Figure 2, A and B). While depletion of AP1 and AP2 had no effect on DENV RNA replication as measured by subgenomic replicon assays (ref. 34 and Figure 2C), it diminished the production of infectious virus in culture supernatants (Figure 2D). Silencing expression of AAK1 and GAK resulted in no apparent cytotoxic effect (Figure 2, E and F) but, analogously to experiments with HCV, inhibited entry and infectious virus production of DENV, with no effect on RNA replication (Figure 2, G–I). These results implicate AAK1 and GAK in the DENV life cycle via regulation of 2 temporally distinct steps that depend on the clathrin-associated APs: entry and infectious virus production.

To determine whether a comparable effect on DENV infection can be achieved pharmacologically and further validate AAK1 and GAK as antiviral targets, we treated DENV-infected cells with selective AAK1 and GAK inhibitors. The imidazo[1,2-b]pyridazine-based compounds 7737 and 7745 were originally developed

Analysis of TC-core puncta stained with the biarsenical dye FIAsH revealed that a large fraction of motile TC-core cotrafficked with either AP1 (25%) or AP2 (38%), whereas only 3% cotrafficked with the autophagosomal marker LC3 (Figure 1, G and H, Supplemental Figure 1A, and Supplemental Videos 1–3; supplemental material available online with this article; https://doi.org/10.1172/JCI89857DS1). The velocities of the cotrafficking particles were consistent with previous reports on secretory vesicle trafficking as well as TC-core puncta cotrafficking with vesicle-associated membrane protein (VAMP) (refs. 32, 33, and Supplemental Figure 1B). AP2-associated TC-core puncta motility was reduced significantly upon mutation (Y136A) of a YxxΦ motif within core, a motif critical for AP2 binding and HCV assembly (22), as measured by the overall distance traveled (Figure 1I and Supplemental Video 4). These findings provide direct experimental evidence for a role of clathrin-associated APs in mediating intracellular virus trafficking. Specifically, these imaging data combined with our current and previous characterization of the roles of AP1 and AP2 in the life cycle of HCV (22, 23) support the hypothesis that AP1 cotraffics with HCV during viral release, while AP2 cotraffics with HCV during viral entry and subsequently to the sites of assembly.

To understand whether drug modulation of AP phosphorylation by AAK1 and GAK manifests itself in an intracellular trafficking defect, we studied the effect of sunitinib and erlotinib, approved drugs with potent anti-AAK1 and/or anti-GAK activity, on HCV particle trafficking by live cell imaging. Treatment of HCV-infected cells with sunitinib and erlotinib reduced motility of TC-core puncta cotrafficking with AP1 and AP2 (Figure 1J and Supplemental Videos 5–10). These findings support our hypothesis that the antiviral effect of sunitinib and erlotinib is associated with reduced intracellular viral traffic.

EC_{50}, half-maximal effective concentration; CC_{50}, half-maximal cellular cytotoxicity; FFA, focus-forming assay; NE, no effect; CPE, cytopathic effect. Virus abbreviations: WNV, West Nile virus; CHIKV, chikungunya virus; JUNV, Junin virus; RSV, respiratory syncytial virus. Each virus was tested at least twice with 3 or more technical replicates.
over, treatment of Vero cells with sunitinib and erlotinib resulted in a dose-dependent decrease in rVSV-GP EBOV infection measured by flow cytometry 20 hours after infection and entry measured by quantitative reverse transcriptase PCR (qRT-PCR) 3 hours after infection (Figure 4D and Supplemental Figure 5B). Although the effect of erlotinib measured by flow cytometry was modest relative to that of sunitinib, combination treatment displayed measurable synergy in inhibiting entry with a synergy volume of 147.05 μM²% at the 95% CI and zero synergistic toxicity (Figure 4, E and F). Next, we tested the ability of these drugs to inhibit authentic EBOV infection in Huh7 cells. Sunitinib treatment resulted in a dose-dependent reduction in EBOV infection with EC₅₀ value of 0.47 μM and CC₅₀ greater than 10 μM, whereas erlotinib showed moderate activity with EC₅₀ of 12.9 μM and no appreciable cytotoxicity at the concentrations tested (Figure 4G and Table 1).

To explore more broadly the spectrum of coverage provided by sunitinib and erlotinib, we studied their antiviral effects against additional unrelated viruses. Viral infection was measured in various cell lines following 3-day treatment regimens. We detected antiviral activity of either or both drugs against RNA viruses in 6 families (Table 1), including Togaviridae (e.g., chikungunya virus [CHIKV]), Arenaviridae (e.g., Junin virus [JUNV]), and Paramyxoviridae (e.g., respiratory syncytial virus [RSV]). These data expand the possible indications of sunitinib and/or erlotinib as antiviral agents beyond Flaviviridae infections, to other established and emerging RNA viruses.

Sunitinib/erlotinib combinations are effective in vivo. To address the therapeutic potential of sunitinib and erlotinib as antiviral agents, we tested their application in a murine model of dengue. We measured viral burden and mortality in an IFN-α/β and IFN-γ receptor–deficient murine model of dengue on 129/Sv (AG-129) (40, 41) and C57BL/6 (AG-B6) genetic backgrounds. In a prophylaxis model, we initiated once-daily treatment of AG-B6 mice with 30–60 mg/kg of sunitinib and erlotinib in combination or individually concurrently with DENV inoculation and analyzed viremia at 48 hours. The doses tested for each drug were at or near the equivalent of approved human dose as calculated based on the body surface area per the FDA’s guidelines (42). These doses were below the maximum tolerated dose (MTD) in mice and confirmed to be nontoxic in our dengue model (42–44). Treatment with erlotinib did not alter viremia, whereas sunitinib alone marginally reduced it (Figure 5A). Consistent with our in vitro synergy results, daily administration of the combination treatment resulted in 11-fold reduction in viral RNA (Figure 5A). In addition, we measured a significant reduction of the infectious virus load by plaque assays in the serum as well as spleen and liver in mice treated with 30 mg/kg doses of sunitinib and erlotinib relative to vehicle controls (Supplemental Figure 6A). Pharmacokinetic analysis revealed that within the first 6 hours of administration each drug concentration in the serum, as measured by liquid chromatography-tandem mass spectrometry, exceeded the

Figure 4. Inhibition of AAK1 and GAK suppresses EBOV infection. (A) Confirmation of siRNA-mediated gene expression silencing by quantitative PCR in Vero cells. Shown is normalized gene expression relative to GAPDH at 48 hours after transfection. (B and C) Relative cell viability measured by alamarBlue assays (B) and rVSV-GP EBOV infection of Vero cells measured by flow cytometry (C) at 20 hours after infection of AAK1- and GAK-depleted cells. ***P < 0.001 relative to NT (1-way ANOVA followed by Dunnett’s multiple comparisons test). (D) Dose response of rVSV-GP EBOV infection to 4-hour treatment with inhibitors measured by flow cytometry at 20 hours after infection in Vero cells. (E and F) Synergy/antagonism of sunitinib/erlotinib combination treatment on rVSV-GP EBOV infection (E) and cell viability (F). (G) Dose response to drug treatment in Huh7 cells under biosafety level 4 containment following 48 hours with EBOV infection (black) measured by immunostaining with an anti-GP antibody, and cell viability (blue) measured by Hoechst counterstain and quantified by a high-content imager. Data are plotted relative to vehicle control. All data shown are representative of at least 2 experiments; B–G have 3 biological replicates each. Shown in B–D and G are means ± SD.
corresponding EC\textsubscript{50} concentration deduced from our in vitro data (Supplemental Figure 6B). Moreover, the synergy between sunitinib and erlotinib predicts even more potency in combination. Although sunitinib and erlotinib were largely cleared from the serum by 18 hours, which is in contrast with the slower clearance rates reported in humans (44, 45), both drugs concentrate severalfold within tissues where DENV replicates, such as liver (46, 47). To maintain higher serum drug concentration, we next administered 30 mg/kg drug combination at 12-hour intervals and measured viremia. The twice-daily drug administration resulted in an even more apparent reduction of viral load relative to vehicle control (Figure 5B). Notably, drug administration reduced viral load from day 2 to 3 postinfection in contrast to an increase in viral load within the control arm during that time.

To assess whether the reduction in viral load would translate into improved disease outcome, we determined the effect of combination treatment with sunitinib and erlotinib on morbidity and mortality in AG-129 and AG-B6 mice. Following infection with a lethal DENV inoculum, we initiated once-daily drug administration at a dose sufficient to significantly reduce viremia (i.e., 30 mg/kg of each drug). The animals were monitored twice daily and were euthanized when moribund (48). The experiment was...
treatment proved efficacious with either i.p. or oral administration, the latter of which is approved for use in humans (Figure 5, C and D). We also compared the effect of daily treatment with the individual drugs with that of the combination. In this trial, 94% of vehicle-treated AG-129 mice succumbed to infection; treatment with erlotinib did not alter survival, whereas sunitinib alone offered partial (37%) protection. Consistent with our in vitro synergy results, we observed the greatest protection (62%) from concluded when all the remaining animals regained full mobility and displayed weight gain for at least 2 consecutive days.

Upon a 5-day drug treatment regimen given either i.p. or orally, we observed a significant reduction in morbidity and mortality of infected animals relative to vehicle controls (Figure 5, C and D). Specifically, 100% of vehicle-treated mice succumbed to infection on day 4–8 postinfection, whereas sunitinib/erlotinib treatment protected 75%–100% of the mice. This combination treatment proved efficacious with either i.p. or oral administration, the latter of which is approved for use in humans (Figure 5, C and D). We also compared the effect of daily treatment with the individual drugs with that of the combination. In this trial, 94% of vehicle-treated AG-129 mice succumbed to infection; treatment with erlotinib did not alter survival, whereas sunitinib alone offered partial (37%) protection. Consistent with our in vitro synergy results, we observed the greatest protection (62%) from

Figure 6. Mechanisms underlying the antiviral effect of sunitinib and erlotinib in vitro and in vivo. (A–C) Huh7 cells were treated with the inhibitors and monitored for DENV entry (A) at 6 hours after infection, DENV RNA replication (B) after induction of replication of DNA-launched DENV replicon, and infectious virus production (C) at 48 hours after electroporation with DENV RNA. SDM25N is an inhibitor of DENV RNA replication. (D) Effect of 1-hour treatment with erlotinib (E) and/or sunitinib (SM) on phosphorylation of AP2 in DENV-infected Huh7 cells measured by Western blotting. Arrow indicates approximately 50 kDa. The ratio of phospho-AP2 (pAP2) to total AP2 was quantified. (E) Level of AP2 and actin expression measured by Western blot following lentiviral transduction with control or AP2-expressing constructs. (F) Rescue of DENV infection in the presence of inhibitors upon overexpression of WT or T156A AP2 versus vector control measured by luciferase assays 48 hours after infection. Micromolar concentration of each inhibitor is noted on the x axis. (G) Effect of 3-hour i.p. treatment with erlotinib (E) and/or sunitinib (SM) on phosphorylation of AP2 in liver tissue of AG-129 mice measured by Western blotting and quantified as the ratio of pAP2 to total AP2. (H) DENV infection relative to NT control following siRNA-mediated knockdown of kinases targeted by sunitinib and erlotinib measured by luciferase assays at 48 hours and normalized to cell viability. Data in A, C, and I are pooled from 2 independent experiments with 4–8 replicates each. Data in the other panels are representative of 2 or more independent experiments. B and F have at least 5 replicates each. ***P < 0.001 relative to DMSO by 2-way ANOVA followed by Dunnett’s multiple comparisons test (B) or relative to vector control by 1-way ANOVA followed by Dunnett’s multiple comparisons test (F).
By direct-acting antivirals (7), was not affected by these drugs. Notably, DENV RNA replication, a step commonly inhibited via siRNAs against AAK1 and GAK (Figure 2, G and I), namely entry and infectious DENV production (Figure 6, A–C). To better understand the target(s) and mechanism of action underlying the anti-DENV activity of sunitinib in vitro and in vivo, we first probed the steps of the viral life cycle and act as broad-spectrum antivirals.

Mechanisms underlying the antiviral effects of sunitinib and erlotinib in vitro and in vivo. To better understand the target(s) and mechanism of action underlying the anti-DENV activity of sunitinib and erlotinib, we first probed the steps of the viral life cycle affected by these compounds. We detected interference precisely with the steps inhibited via siRNAs against AAK1 and GAK (Figure 2, A–C). Notably, DENV RNA replication, a step commonly inhibited by direct-acting antivirals (7), was not affected by these drugs. This phenotype supports a hypothesis that inhibition of AAK1 and GAK likely contributes to the anti-DENV effect of these drugs.

To confirm that the antiviral activity is correlated with functional inhibition of AAK1 and GAK activity, we measured levels of phospho-AP2 upon drug treatment. Dose-dependent reduction in the phospho-AP2 to total AP2 ratio was demonstrated in DENV-infected cells (Figure 6D).

Next, we conducted gain-of-function assays to further validate AP2, a substrate for both AAK1 and GAK, as a key mediator of the anti-DENV effect of these drugs. Ectopic expression of WT but not T156A phosphorylation AP2 mutant or vector control either partially or completely rescued the antiviral effect of sunitinib/erlotinib combination (Figure 6, E and F). These results indicate that AAK1- and GAK-mediated phosphorylation of AP2 is a mechanism underlying the antiviral effect of sunitinib and erlotinib against DENV.

Next, we determined whether these drugs exert their antiviral effect in vivo by similarly inhibiting phosphorylation of the AAK1 and GAK ligand AP2. Liver tissue lysates harvested from AG-B6 mice 3 hours after drug administration revealed dose-dependent inhibition of AP2 phosphorylation upon treatment with sunitinib and erlotinib, and most markedly with the combination (Figure 6G). These results provide evidence that drug exposure in animals is associated with modulation of AP2.

These data, combined with the finding that more selective AAK1 and GAK inhibitors lacking affinity to most of sunitinib’s and erlotinib’s cancer targets (e.g., VEGFR and EGFR) (28, 35) have anti-DENV activity, indicate that AAK1 and GAK are important mediators of the observed antiviral effect. Nevertheless, these data cannot rule out additional potential cellular targets mediating the anti-DENV activity of these compounds. Whereas erlotinib’s target selectivity is quite narrowly focused on EGFR and GAK with significantly less affinity for other kinases, sunitinib is a multitarget kinase inhibitor (49, 50). We thus examined the effects of siRNA-mediated depletion of 27 major kinases targeted by these small molecules (K_i < 20 nM) on DENV infection and cellular viability. Using a cutoff of greater than 50% inhibition of viral infection as measured by luciferase assays normalized to cell viability in 2 independent screens, we identified AXL, KIT, and RET as possible antiviral targets of our kinase inhibitors in addition to AAK1 and GAK (Figure 6H).

Taken together, our data indicate that inhibition of AP-mediated intracellular membrane trafficking regulated by AAK1 and GAK represents an important mechanism by which sunitinib and erlotinib inhibit DENV infection in vitro and in vivo and that additional mechanisms, potentially mediated by other kinases, may act in concert.

Discussion

Clathrin-associated AP1 and AP2 complexes have been implicated in orchestrating multiple viral infections; however, their precise mechanistic involvement was not characterized. Moreover, the relevance of AAK1 and GAK, kinase regulators of these APs that we discovered as essential for HCV infection, to other viral infections remained unknown. Here, we addressed this knowledge gap and evaluated the therapeutic potential of inhibiting AAK1 and GAK as a broad-spectrum antiviral strategy. Integrating RNAi, dominant interfering, pharmacological and molecular virology
approaches, we demonstrate roles for AP1 and AP2 complexes as well as AAK1 and GAK in entry and assembly/release of Flaviviridae family members and validate these host factors as attractive targets for broad-spectrum antiviral therapy (Figure 7). We established that sunitinib and erlotinib inhibit DENV and EBOV infections in vitro and in vivo, and are potent in vitro against WNV, ZIKV, and RNA viruses from 4 additional families: Togaviridae, Arenaviridae, Paramyxoviridae, and Retroviridae. Together, our data illustrate the utility of these 2 clinically approved compounds both as tools to identify host factors important in viral infection and as potential therapies against emerging viral infections.

Using advanced live cell imaging, we provide the first direct evidence, to our knowledge, that viral particles cotraffick intracellularly with AP complexes. Our imaging findings exclude a theory whereby AP complexes contribute to viral infections solely by recruiting or mediating intracellular traffic of host cargo components essential for the viral life cycle.

We show that sunitinib and erlotinib, potent, albeit nonselective, inhibitors of AAK1 and GAK, respectively, restrict DENV and EBOV infections in vitro and their combination reduces viremia, morbidity, and mortality in the relevant murine models. Replication assays demonstrating efficacy against viral species in 6 unrelated families (Table 1) further support our broad-spectrum hypothesis, though in vivo efficacy beyond dengue and Ebola remains to be tested. AAK1 and GAK have partially overlapping functions (12, 23), which may explain moderate antiviral effect in vitro with either sunitinib or erlotinib, yet synergistic activity upon treatment with both. The synergy also may result from inhibition of additional targets by these compounds. Although the observed reduction in DENV load was relatively modest in mice, it correlated with a significant survival benefit, comparable to the report on host α-glucosidase inhibitor celgosivir (51), which yielded 100% protection from mortality with less than 10-fold reduction in viremia. Importantly, the sunitinib/erlotinib combination remained protective in the mouse model of dengue even when administered after established infection, thereby supporting its promise as both prophylaxis and therapy.

We provide multiple lines of evidence to support modulation of AAK1 and GAK activity as an important mode of antiviral action of sunitinib and erlotinib in the dengue model. We demonstrate that these drugs inhibit both DENV entry and infectious virus production, analogous to the phenotype seen with RNAi-mediated suppression of clathrin-associated APs and AAK1 and GAK. Additionally, we demonstrate antiviral effects of more selective AAK1 and GAK inhibitors. Due to lack of affinity to most of sunitinib’s and erlotinib’s cancer targets (e.g., VEGFR and EGFR) (28, 35), the activity of the selective compounds further confirms that AAK1 and GAK are relevant antiviral targets. While the more selective GAK inhibitors also bind KIT, more work is required to validate whether KIT is an anti-DENV target. Furthermore, we characterized the mechanism by which the pharmacological inhibition of AAK1 and GAK mediates the anti-dengue effect. We establish that antiviral activity of sunitinib and erlotinib correlates with reduced phospho-AP2 levels in vitro. In accordance with this observation, we show that WT but not a phosphorylation AP2 mutant can rescue the anti-dengue effect of these drugs. We provide evidence that this mechanism also plays a role in vivo by demonstrating that antiviral activity correlates with reduced AP2 phosphorylation in tissues upon drug treatment. These findings reveal that a block in AP2 phosphorylation mechanistically explains at least in part the antiviral effect of AAK1 and GAK inhibitors. These findings also present AP2 phosphorylation as a useful pharmacodynamic biomarker in potential future clinical studies. We further demonstrate that sunitinib and erlotinib reduce HCV-AP1 and -AP2 cotrafficking by live cell imaging, thereby validating this mode of action at the molecular level. While AP-mediated intracellular membrane trafficking likely represents a primary mechanism by which AAK1 and GAK regulate viral infection, additional substrates of these kinases, such as NUMB, also may contribute to this function (23).

We speculate that inhibition of AAK1 and GAK accounts for these drugs’ effect against a broad spectrum of viruses, particularly those previously shown to depend on AP1 and AP2 activity, such as EBOV (18, 37–39). Inhibition of additional kinases including AXL, KIT, and RET may facilitate DENV infection and thus potentially also mediate sunitinib’s antiviral effect. AXL is an already known attachment factor/signaling receptor for multiple RNA viruses, including DENV, EBOV, and possibly ZIKV (52–55). Although confirmatory studies with AXL-deficient cells are required, inhibition of AXL by sunitinib may contribute to its effect on DENV entry. KIT and RET are paralogs with no reported roles in RNA viral infections and await further investigation. Given our inability to silence expression of KIT without a substantial negative impact on cell viability (likely due to its role in cell survival and proliferation; ref. 56), its specific relevance to DENV infection remains unclear. Overall, our data underscore the utility of using sunitinib and erlotinib as pharmacological probes to identify novel host factors required for viral infection.

Although toxicity is a concern when targeting host functions, finding a safe therapeutic window may be feasible. Sunitinib and erlotinib each are approved as a once-daily oral treatment for multiple cancers at doses comparable to those exhibiting antiviral activity in vivo. A combination therapy already has been evaluated clinically and was tolerated, albeit with an increase in the adverse events primarily related to gastrointestinal disturbances (57, 58). However, a shift from the long-term treatment of cancer to acute infection such as with DENV should improve tolerance and minimize adverse effects. The safety and efficacy of sunitinib and/or erlotinib will be evaluated in dengue patients in the near future and potentially in patients with EBOV disease in future outbreaks (ClinicalTrials.gov NCT02380625).
The vast genetic diversity of viral species and replication strategies challenges the design of broadly effective direct-acting antivirals; however, a host-targeted approach could circumvent this issue. Sunitinib and erlotinib inhibit all 4 DENV serotypes. Moreover, a broad-spectrum therapy, such as with sunitinib/erlotinib combination, could be used to treat DENV-CHIKV (59, 60) or DENV-ZIKV (61) coinfections and infections with newly emerging RNA viruses. It also can be administered even before an accurate diagnosis of a viral threat, thereby increasing protection. Furthermore, although viral resistant mutations can emerge during treatment with host-targeted approaches (62), targeting of host proteins that are not under the genetic control of viruses is more likely to have a higher barrier to resistance than classical direct-acting antivirals. This is exemplified by our data and treatment with cyclophilin inhibitors (63). We recognize, however, that our dengue resistance assay is somewhat limited by the short-term virus passage. Although we predict that the genetic barrier to resistance is high, it may be possible to select for resistance over longer-term passage under different conditions or in a different, chronic infection model. Lastly, viruses use strategies similar to those of cancer cells for overcoming drug-mediated inhibition. Simultaneous inhibition of several kinases or targeting of several pathways by the same drug or drug combination may prove attractive in combating viral pathogens, as previously shown in cancer (64). Such “polypharmacology” by a single drug could increase the effectiveness while minimizing viral resistance.

In summary, our study serves as a proof of concept for the feasibility of identifying novel host-targeted broad-spectrum antiviral therapies via both repurposing and development of novel chemical entities. Such approaches may provide additive and possibly synergistic effects in combination with other strategies being developed to combat emerging viral infections.

Methods

Plasmids and virus constructs. ORFs encoding APIM1 (AP1) and AP2M1 (AP2) were selected from the Human ORFeome library of cDNA clones (65) (Open Biosoystems) and recombined into either pCherry (for mCherry fluorescence protein tagging) or pGLuc (for Gaussia Princeps luciferase fragment [GLuc] tagging) vectors using Gateway technology (Invitrogen). GFP-LC3 construct was previously described (66). Plasmids used in the HCVpp entry assays (pNL4-3.Luc.R-E, pcDM8, and pCDM8-E1E2) were a gift from Shoshana Levy (Stanford University, Stanford, California, USA). DENV2 TSV01 Renilla reporter construct used in the HCVpp entry assays (pNL4-3.Luc.R-E, pcDM8, and pCDM8-E1E2) was a gift from Sujan Shresta (70, 71). pCMV-DV2Rep was a gift from Andrew Yueh (Institute of Biotechnology and Pharmaceutical Research, Taipei, Taiwan) (34). Mutations were introduced by site-directed mutagenesis using the QuikChange kit (Stratagene).

Cells. Huh7 (Apath LLC), Huh7.5 (Apath LLC), BHK-21 (ATCC), and Vero (ATCC) cells were grown in DMEM (Mediatech) supplemented with 10% FBS, nonessential amino acids (Gibco), 1% L-glutamine (Gibco), and 1% penicillin-streptomycin (Gibco) and maintained in a humidified incubator with 5% CO₂ at 37°C. C6/36 cells were grown in Leibovitz’s L-15 media (CellGro) supplemented with 10% FBS and 1% HEPES in a humidified chamber at 28°C and 0% CO₂.

Reagents. The following reagents were used: sunitinib malate (Selleckchem), erlotinib (LC Laboratories), Captisol (Captisol), silmporter (Millipore), and Lipofectamine 2000 (Invitrogen). 12g and 12i were synthesized by the Herdewijn laboratory (28); 7737 and 7745 were synthesized by ACME Bioscience Inc.

Western blotting and antibodies. Cells were lysed in M-Per protein extraction reagent (Thermo Fisher Scientific). For phosphoprotein detection, cells were pretreated with 100 nM calyculin A (Cell Signaling), a PPI and PP2a phosphatase inhibitor, for 30 minutes prior to lysis. Liver tissue was homogenized in RIPA buffer supplemented with Halt protease and phosphatase inhibitor cocktail (Thermo Fisher Scientific) and 100 nM calyculin A using 0.9- to 2-mm stainless steel beads in a BBX24 Bullet Blender homogenizer (NextAdvance). Clarified protein lysates were run on 4%-12% Bis-Tris gels (Invitrogen), transferred onto PVDF membranes (Bio-Rad). Blots were blocked and blotted with anti-APIM1 (Abcam, catalog ab111335), anti-AP2M1 (Abcam, catalog ab75995), anti-GLuc (New England BioLabs, catalog E8023S), anti-phospho-AP2M1 (T156) (Cell Signaling, catalog 3843S), anti-AAK1 (Abcam, catalog ab134971), anti-GAK (MBL International, catalog MO573), and anti-β-actin (Sigma-Aldrich, catalog A3854) antibodies. Signal was detected with HRP-conjugated secondary antibodies. Band intensity was quantified with ImageJ software (NIH). See complete unedited blots in the supplemental material.

RNA interference. siRNAs (100–250 nM) were transfected into cells using siMPORTER (Millipore) 48 hours before infection. Sequences/catalog numbers are as follows: human AAK1 and GAK, Silencer Select predesigned siRNA ID#s#22949 and s5529, respectively (Thermo Fisher Scientific); Chlorocebus sabaeus (green monkey) AAK1 siRNA#1, GGUAUAUGUUGAAACCGATG; AAK1 siRNA#2, GAAAUUUUGGGUUUCAUTT; GAK siRNA#1, GCAUAAGAG-GCUAAUUTT; GAK siRNA#2, CAGCAUAUGGAAAGGATT; NT, Silencer Select negative control (Thermo Fisher Scientific, catalog 4390844). Infections were performed at 48 hours after transfection. APIM1 and AP2M1 were silenced via transduction with shRNA-expressing lentivirus (TRCN00000218336, TRCN0000060239, or Mission pLKO.1-puro nonmammalian shRNA control; Sigma-Aldrich) and selection on 1 μg/ml puromycin. Custom Cherry-Pick ON-TARGETplus siRNA library against 27 kinase genes was purchased from Dharmacon (see Supplemental Table 1 for gene and siRNA sequence details).

Virus production. HCV 2a J6/JFH(p7-Rluc2A) was transcribed in vitro using Megascript T7 kit (Ambion), and DENV2 TSV01, 16681 (used for DENV in vitro assays), or N124D/K128E DENV2 PLO46 (used for DENV in vivo infections) RNA was transcribed in vitro using Message/mMachine (Ambion) kits. HCVcc and HCVpp were produced as previously described (23). DENV was produced by electro-
poration of RNA into BHK-21 cells, harvesting of supernatants at day 10, and titering via standard plaque assays on BHK-21 cells. In parallel, on day 2 after electroporation, DENV-containing supernatant was used to inoculate C6/36 cells to amplify the virus. For in vivo experiments, DENV supernatant was concentrated 100-fold by centrifugation at 50,000 g. rVSV-GP EBOV was propagated and titered on Vero cells via fluorescent-focus assay (69).

Entry assays. Huh7.5 cells were infected with HCVpp (71, 72) and 8 μg/ml Polyperene for 4 hours. Firefly luciferase activity was measured at 48–72 hours after infection. DENV2 entry was measured at 6 hours after infection of Huh7 cells by monitoring of Renilla luciferase activity. Luminescence was detected on InfiniteM1000 plate reader (Tecan). Vero cells were infected with rVSV-GP EBOV for 3 hours, total RNA was harvested and reverse transcribed, and EBOV GP transcript was quantified by real-time PCR and normalized to GAPDH expression.

Infection assays. Huh7 cells were infected with DENV or ZIKV in replicates (n = 3–10) for 4 hours at MOI of 0.01. Overall infection was measured either at 48 hours using a Renilla luciferase substrate or at 72 hours by plaque assays. Vero cells were infected with rVSV-GP EBOV for 4 hours and washed. At 20 hours after infection, cells were fixed with 4% formaldehyde and analyzed on an LSR II cytometer (BD Biosciences) using FITC channel. Data were processed using FlowJo software. EBOV infection was carried out under biosafety level 4 conditions. Forty-eight hours after infection, cells were formalin-fixed, and infection was measured by immunofluorescence using KZ52 anti-EBOV antibody in an Operetta HCS using the Harmony software package. Other viral infection assays, conducted by the Diamond lab (WNV), IBT BioServices (CHIKV, RSV, JUNV), and the NIH/National Institute of Allergy and Infectious Diseases (others), were performed as summarized in Table 1.

RNA replication assays. HCV RNA replication was measured 72 hours after electroporation, as previously described (22). DENV2 replication assays were performed as previously described (34). Briefly, Huh7 cells were transfected with DNA-launched DENV2 replicon, pCMV-DV2Rep along with TET-ON plasmids. Thirty-six hours after transfection, viral RNA transcription was induced by doxycycline and shut down by changing to doxycycline-free medium 6 hours later. Replication was monitored by luciferase activity every day for 3 days. Data were normalized to activity at 24 hours after induction.

Infectious virus production. Infectious HCV or DENV production (i.e., extracellular infectivity) was measured in culture supernatants of cells electroporated with viral RNA for 48–72 hours and used to infect naive cells for 48 hours. Intracellular HCV infectivity was measured by inoculation of naive cells with lysates of electroporated cells subjected to 4 rounds of free-thawing and clarified at 5,000 g, as previously described (22).

Pharmacological inhibition. For entry assays, cells were pretreated with the inhibitors or DMSO for 1 hour before and for the duration of the infection, followed by replacement with drug-free medium. For the overall infection, RNA replication, or infectious virus production assays, inhibitors were left in for the duration of the study.

Gain-of-function assays. WT or T156A AP2 or empty vector control was expressed ectopically in Huh7 cells by lentiviral transduction. Twenty-four hours after transduction, cells were pretreated with sunitinib and erlotinib, infected with luciferase reporter DENV at MOI of 0.01, and incubated for 72 hours prior to luciferase and viability assays.

Live cell imaging. Huh7.5 cells were infected with concentrated HCV TC-core (32) at MOI of 1 for 24 hours, then transfected with either AP1- or AP2-mCherry using Lipofectamine 2000 (Invitrogen) and seeded onto collagen-coated 35-mm fluorodishes (World Precision Instruments). At 72 hours after infection, cells were labeled with biarsenical dye (1.25 μM) in Opti-MEM at 37°C for 30 minutes, then washed 3 times with 1X BAL (2,3-dimercapto-1-propanol) wash buffer (Invitrogen) supplemented with 500 μM 1,2-ethanediolthiol in Opti-MEM. The cells were washed and incubated in prewarmed imaging media (DMEM-F12; Invitrogen) supplemented with 10% FBS, 0.1 mM nonessential amino acids, 1% penicillin-streptomycin, and 25 mM HEPES. When specified, TC-core–infected cells were incubated with DMSO, sunitinib (4 μM), or erlotinib (10 μM) beginning at 24 hours after infection. Time-lapse images were taken using a Leica SP5 II AOBS Tandem Scanner Spectral confocal microscope with a ×100 1.46 oil objective and a heated (37°C) chamber. An average of 5 movies representing individual cells with 15–30 trackable puncta each were recorded per sample with sequential frames taken every 2 seconds. Individual core puncta run lengths and transport velocities were calculated using the Manual Tracking plug-in for ImageJ, measuring the distance traveled (in any direction) between frames for a respective TC-core puncta.

Resistance studies. DENV4 (BC287/97; ATCC/BEI Resources, BEI NR-3806) was used to inoculate Huh7 cells at MOI of 0.01 and passaged every 3 days by transferring of an equal volume of viral supernatant to naive cells under increasing drug selection (0.5–1.5 μM, passages 1–6; 2.5 μM passages 7 and 8). Upon completion of 8 passages, virus from the resulting supernatants was titered by plaque assays. SDM25N resistance mutation in NS4B at passage 8 was confirmed by purification and reverse transcription of viral RNA from supernatants of cells treated with DMSO or SDM25N as described in the RNA extraction and quantification section. NS4B region was amplified with iProof high-fidelity PCR kit (Bio-Rad) using primers NS4B forward GATGTTGAGACCGACGCCAGCATGGAC and NS4B reverse AGTCAANCTTCACGAAAGCCCATGTGTTCTCATCA (N = any base, Y = C or T) and sequenced (Sequetech Corp.).

In vivo dengue studies. AG-129 mice deficient in type I and II IFN receptors were obtained from Harry Greenberg (Stanford University, Stanford, California, USA). Mice were backcrossed to C57B6/6j for n = 10 generations to obtain congenic AG-B6 strain. Age-matched, male and female mice at 8–10 weeks of age were used for all experiments. Mouse-adapted N124D/K128E DENV2 (5 × 105 PFU produced in BHK-21 cells or 107 PFU produced in C6/36 cells) was inoculated retro-orbitally into mice under general and local anesthesia. Drugs were administered at the indicated doses in a total volume of 100–200 μl per animal using 10% Captisol as vehicle. Drugs or vehicle were administered i.p. or orally once or twice daily starting at the time of inoculation or at various time points after inoculation for a total of 3–5 days. Mice were monitored twice daily until the conclusion of the experiment. Moribund animals were euthanized by carbon dioxide inhalation. Serum was isolated from whole blood harvested retro-orbitally at 48 or 72 hours after DENV inoculation under general and local anesthesia. Tissues were harvested following euthanasia and snap-frozen on dry ice until further analysis.

In vivo Ebola studies. Groups of 10 female C57BL/6 mice (8–12 weeks of age) purchased from Jackson Laboratory were treated with drugs or vehicle 6 hours before viral challenge. Erlotinib and sunitinib
were administered i.p. at the indicated doses in a total volume of 200 μl using 10% Captisol as vehicle. A group of 10 mice was left untreated to allow for interpretation of any survival seen in the vehicle-treated group. Mice were inoculated i.p. with 100 PFU of mouse-adapted EBOV. Mice were then treated once daily for a total of 10 days and observed daily for 28 days for lethality or clinical signs of disease.

RNA extraction and quantification. Total RNA from cells was isolated using an RNA purification kit (Macherey-Nagel). Mouse serum was purified from whole blood using Terumo Capiject Capil-lary Blood collection tubes (Thermo Fisher Scientific). Tissues were homogenized using 0.9- to 2-mm stainless steel beads in a BBX24 Bullet Blender homogenizer (NextAdvance). Total RNA from serum and tissues was extracted with QIAamp UltraSens Virus kit (Qiagen). cDNA was generated using a high-capacity cDNA reverse transcription kit (Invitrogen). DENV RNA was quantified by qRT-PCR using TaqMan GEX master mix (Thermo Fisher Scientific), and AAK1, GAK, EBOV GP, and housekeeping gene (GAPDH) RNA was quantified using iTaq Universal SYBR Green Supermix (Bio-Rad) on a StepOnePlus real-time PCR system (Applied Biosystems). Primer and probe sequences are as follows: DENV2 forward, GATGCCACACCTGCAG; DENV2 reverse, GTATCGAAACCCGAGAAACGG; GAPDH forward, GAAATCCCATCACCATCTTCCAG; GAPDH reverse, GAGCCCCACGCTTCTCCATG.

Viability assays. Viability was assessed using alamarBlue reagent (Invitrogen) according to the manufacturer’s protocol. Fluorescence was detected at 560 nm on an InfiniteM1000 plate reader (Tecan).

Data analysis of combination drug treatment. Synergy/antagonism analysis was performed using the MacSynergy II program as previously described (23, 73). Matrix data sets in 4 replicates were assessed at the 95% confidence level for each experiment. Synergy and log volume were calculated. As suggested by Prichard et al. (73), such data sets should be interpreted as follows: volumes of synergy or antagonism at values less than 25 μM% are insignificant, those of 25–50 μM% are minor but significant, those of 50–100 μM% are moderate and probably important in vivo, and those of greater than 100 μM% are strong and likely to be important in vivo.

Statistics. All data were analyzed with GraphPad Prism software. Fifty percent effective concentrations (EC50) were measured by fitting of data to a 3-parameter logistic curve. P-values were calculated by 2-tailed unpaired t test and 1- or 2-way ANOVA with either Dunnett’s or Tukey’s multiple comparisons tests for in vitro data sets and by Mann-Whitney test for in vivo data sets as specified in each figure legend. Survival curve P-values were calculated by log-ranked Mantel-Cox test.

Study approval. Animal research was conducted under a protocol approved by Stanford’s IACUC (Administrative Panel on Laboratory Animal Care) and its Institutional Biosafety Committee (Administrative Panel on Biosafety) or by the US Army Medical Research Institute of Infectious Diseases (USAMRIID) IACUC in compliance with the Animal Welfare Act and other federal statutes and regulations relating to animals and experiments involving animals. The Stanford and USAMRIID animal facilities are AAALAC-accredited and adhere to the principles stated in the 2005 Guide for the Care and Use of Laboratory Animals (National Academies Press). DENV and EBOV challenge studies were conducted in a biosafety level 2 (BSL-2) and a maximum-containment BSL-4 facility, respectively. Moribund mice were humanely euthanized on the basis of IACUC-approved criteria.

Author contributions
SE, EB, GN, AS, SYP, JB, RBB, JG, MSD, JMD, and GR conceived and designed the experiments. EB, GN, AS, SYP, JB, SW, FX, RBB, JG, RBB, and CMN performed the experiments. SE, EB, GN, AS, SYP, JB, SW, FX, RBB, JG, MSD, JMD, and GR analyzed the data. RM, CMN, SD, and PH contributed reagents/materials/models. EB and SE wrote the manuscript. SE supervised the overall project.

Acknowledgments
This work was supported by award 1U19 AI10966201 (Centers of Excellence for Translational Research) from the National Institute of Allergy and Infectious Diseases (NIAID) to SE, NIAID U19 AI083019 to MSD, grant RSG-14-11-0-01-MPC from the American Cancer Society to SE and GR, and grants from Stanford Bio-X, the Stanford SPARK program, and the Stanford Translational Research and Applied Medicine program. In vitro studies were also supported by grant 2013100 from the Doris Duke Charitable Foundation and grant PR151090 from the Department of Defense office of the Congressionally Directed Medical Research Programs. GN was supported by the Child Health Research Institute, Lucile Packard Foundation for Children’s Health, as well as the Stanford Clinical and Translational Science Award (CTSA, grant UL1 TR000093). SYP was supported by Taiwan Ministry of Science and Technology grant 103-2917-I-564-033. JMD’s work acknowledges the support of the Joint Science and Technology Office-Defense Threat Reduction Agency (CB3958) in completion of the live virus experiments. The opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the US Army or the other funders. We thank Scott Weaver and Robert Tesh for the ZIKV (MR766), Mark N. Prichard for providing the MacSynergy II program, Kartik Chandran for the rVSV-GP EBOV construct, Eva Harris and Karla Kirkegaard for assistance with establishing dengue tissue culture and mouse models in our laboratory, and Alex McMillan (with support from CTSA UL1 TR001085) for assistance with the statistical analysis.
