Ultrasound-guided lumbar medial branch blocks and intra-articular facet joint injections: a systematic review and meta-analysis

Zachary M. Ashmore, Michael M. Bies, James B. Meiling, Rajat N. Moman, Leslie C. Hassett, Christine L. Hunt, Steven P. Cohen, W. Michael Hooten

Abstract

There is great interest in expanding the use of ultrasound (US), but new challenges exist with its application to lumbar facet–targeted procedures. The primary aim of this systematic review and meta-analysis was to determine the risk of incorrect needle placement associated with US–guided lumbar medial branch blocks (MBB) and facet joint injections (FJI) as confirmed by fluoroscopy or computerized tomography (CT). An a priori protocol was registered, and a database search was conducted. Inclusion criteria included all study types. Risk of bias was assessed using the Cochrane risk of bias tool for randomized controlled trials and the National Heart, Lung, and Blood tool for assessing risk bias for observational cohort studies. Pooled analysis of the risk difference (RD) of incorrect needle placement was calculated. Pooled analysis of 7 studies demonstrated an 11% RD (P = 0.0009) of incorrect needle placement for US-guided MBB confirmed using fluoroscopy with and without contrast. Pooled analysis of 3 studies demonstrated a 13% RD (P = 0.0001) of incorrect needle placement for US-guided FJI confirmed using CT. The time to complete a single-level MBB ranged from 2.6 to 5.0 minutes. The certainty of evidence was low to very low. Ultrasound-guided lumbar MBB and FJI are associated with a significant risk of incorrect needle placement when confirmed by fluoroscopy or CT. The technical limitations of US and individual patient factors could contribute to the risk of incorrect needle placement.

Keywords: Ultrasound, Medial branch block, Facet joint injection, Systematic review, Meta-analysis

1. Introduction

Fluoroscopy is the most widely used imaging modality for performing lumbar medial branch nerve blocks (MBB) and facet joint injections (FJI). Current Procedural Terminology codes for ultrasound-guided paravertebral injections (0213T-0218T) are considered investigational and experimental, and American Society of Interventional Pain Physicians guidelines mandate the use of fluoroscopy or computed tomography (CT) for facet interventions. However, there has been an effort to increase the use of ultrasound (US) for spine procedures, including sacroiliac joint injections, epidural steroid injections, MBB, and FJI. Proposed benefits of US include lower cost and avoidance of radiation exposure for patients and medical personnel. Although there is great interest in expanding the use of US, there are new challenges with its application to lumbar facet–targeted procedures including increased tissue depth in the lumbar region. The technological limitations of US combined with the tissue depth of lumbar facets may affect the accuracy of needle placement. This is critically important when facet-targeted procedures are used for diagnostic purposes.

The use of US to perform lumbar MBB and FJI and the associated risk of incorrect needle placement have not been previously summarized. The primary aim of this systematic review and meta-analysis was to determine the risk of incorrect needle placement associated with US-guided lumbar MBB and FJI as confirmed by fluoroscopy or CT. Secondary objectives include summarizing the techniques used to perform US-guided
lumbar MBB and FJL, (2) procedure time for performing US-guided lumbar MBB and FJL, and (3) complications.

2. Methods

2.1. Search strategy

This study was performed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines, and the study protocol was registered at the International Prospective Register of Systematic Reviews (PROSPERO) (CRD42020172717) in April 2020. A comprehensive search of databases was conducted from inception to February 1, 2021, and there were no language restrictions. The databases included Ovid MEDLINE(R) and Epub Ahead of Print, In-Process & Other Nonindexed Citations and Daily, Ovid Embase, Ovid Cochrane Central Register of Controlled Trials, Ovid Cochrane Database of Systematic Reviews, and Scopus.

The search strategy was conducted by an experienced librarian with input from the principal investigator. Controlled vocabulary supplemented with keywords was used to search for studies describing US-guided MBB and FJL for low back pain. The detailed strategy listing all search terms used and how they are combined is available in the supplemental materials document (available at http://links.lww.com/PR9/A160).

2.2. Study selection process

Study inclusion criteria included (1) evaluation of US-guided lumbar MBB and FJL, (2) all study designs including conference proceedings and abstracts, and (3) outcomes assessing feasibility, diagnosis, prognosis, or safety. Exclusion criteria included (1) human cadaver or animal studies.

In the first review phase, 2 pairs of reviewers independently screened all titles and abstracts identified by the search strategy. In the second phase, the 2 pairs of reviewers independently screened the full text of all studies and inclusion and exclusion criteria were applied. Any reviewer disagreements were resolved by a third party.

2.3. Data extraction

Data were extracted by 4 independent reviewers using a templated electronic database. Based on the a priori protocol, abstracted data included the year of publication; number of participants; type of intervention; imaging technique used to perform the intervention; and outcomes assessing feasibility, diagnosis, prognosis, or safety. The corresponding authors of selected studies were contacted if missing or incomplete data were reported.

2.4. Risk of bias assessment

Risk of bias was assessed using the Cochrane risk of bias tool for randomized controlled trials (RoB2). The National Heart, Lung, and Blood tools for assessing risk of bias were used for case series and observational cohort studies with and without controls.

2.5. Grading of evidence

The various outcomes assessed in this review were evaluated according to the Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) approach. Domains of evaluation included risk of bias, imprecision, inconsistency, indirectness, and publication bias.

2.6. Evidence synthesis

For each study, the number of needles placed by US guidance for MBB or FJL was recorded and the number of needles confirmed by fluoroscopy or CT to be correctly placed by US guidance was also recorded. Using the inverse variance method, the risk difference of US-guided needle placement as confirmed by fluoroscopy or CT was pooled across all studies using a random effects model. Heterogeneity was expressed using the I² statistic, and results were reported with 95% confidence intervals (95% CI). All statistical analyses were performed using RevMan (Reviewer Manager, version 5.3.5; the Cochran Collaboration, Copenhagen, Denmark).

3. Results

3.1. Characteristics of included studies

A flow diagram of the study selection process is depicted in Figure 1. A total of 22 studies met the inclusion and exclusion criteria (Table 1). Study designs included 6 randomized controlled trials (RCTs), 16,19,25,51,54,55 1 controlled cohort study,43 9 cohort studies,3,13,21,24,28,32,37,47 1 retrospective comparative study,20 3 case series,9,17,40 and 2 case reports.6,41 Four studies were conference proceedings or abstracts,3,9,32,47

3.2. Risk of bias assessment

The full risk of bias assessment is presented in the supplemental materials document (available at http://links.lww.com/PR9/A160). Five RCTs were graded as having some concerns,16,25,51,54,55 while 1 was graded as high risk of bias because of bias in reporting outcomes.19 In the nonrandomized studies, 1 was graded as having good quality,14 8 were graded as having fair quality,3,13,21,24,28,37,40,42 and 4 were graded as having poor quality.9,17,32,47 Significant risk of bias related to nonreporting of study data were identified, and most of the studies did not specify an a priori statistical plan.3,9,13,17,19–21,24,25,32,37,40,43,47,54 Three studies with high risk of bias because of nonreporting of information were conference abstracts.9,32,47 Some studies were susceptible to selection bias because of exclusion of patients with obesity.25,54 For all comparative studies, only 1 study reported that outcome assessors were blinded.14

3.3. Ultrasound-guided medial branch blocks

3.3.1. Technique for performing ultrasound-guided medial branch blocks

The included studies describe T12-L5 MBB (L5 dorsal ramus blocks are herein referred to as MBB) with varying laterality and injectate volumes as detailed in Table 1. For US-guided MBB, 7 studies described a sagittal approach to identify the spinal level for injection followed by a transverse view to identify the target for final needle placement.14,17,20,21,24,37,43 One study only described using the transverse view. All studies which specified the target for needle placement described the junction of the cephalad transverse process and the superior articular process which has been shown in a cadaveric and CT-confirmation study as being less specific than targeting a lower point midway between the upper border of the transverse process and the mamilloaccessory ligament.12 Two studies did not describe the technique for performing the US-guided MBB.3,47 Six studies specified...
injections performed in-plane from a lateral to medial di-
rrection.6,14,17,21,24,37 One study described a reorientation of
needle direction after performing an L4 MBB, in which the
needle was withdrawn and walked medially and caudally while
observing progress towards the target for the L5 MBB
(intersection of sacral ala and superior articular process) in an
out-of-plane fashion.14

Placement of 4 needles was associated with suspected
vascular uptake because of contrast spread only partially
covering target area in one study14 and because of lack of dye
visualization under fluoroscopy in another.43 One study used a
total volume of 0.25 mL, while the other used a total volume of 1
mL. The specific level of suspected intravascular uptake was not
described. The number of patients with these suspected findings
was not specified.

3.3.2. Meta-analysis of ultrasound-guided medial branch
blocks as confirmed by fluoroscopy

Seven studies confirmed needle placement with fluoroscopy
(Table 2).14,17,21,24,37,43 Forest plots of the meta-analysis confirming correct needle placement using
fluoroscopy with and without contrast are depicted in Figure 2.

Pooled analysis demonstrated a 17% RD (95% CI, −0.06 to 0.39,
$P = 0.15$) of incorrect needle placement for US-guided MBB
confirmed using fluoroscopy without contrast with high levels of
heterogeneity identified ($I^2 = 95\%$). Pooled analysis demon-
strated a 7% RD (95% CI, 0.04 to 0.10, $P < 0.0001$) of incorrect
needle placement for US-guided MBB confirmed using

3.3.3. Procedure time for a single-level ultrasound-guided
medial branch blocks

Three studies reported the time needed to perform a single-level
MBB.21,37,43 These studies reported that the average time ranged
from 4.0 to 5.0 minutes.21,37,43 One of these studies also reported
a total procedure time of 5.9 (SD 1) minutes, which may have
included additional time to perform adjacent-level injections.21
Another study reported the time to perform L5 MBB in-plane and
out-of-plane after reorientation of the needle from its position
immediately after L4 MBB. Time for completion of this technique
was reported as 153.93 (SD 41.56) seconds.14 An additional study
reported that the procedure time for performing a US-guided MBB
was significantly shorter compared with fluoroscopy (323 vs 430

seconds, $P < 0.001$). It was not clear from the methods of this study whether performance time was for a single-level or multilevel procedure. Another study reported that the maximum procedure time for multiple blocks at multiple levels was 40 minutes.

### 3.3.4. Complications associated with ultrasound-guided medial branch blocks

Complications were reported in 3 studies. Dizziness and bilateral lower extremity weakness were reported in 1 patient immediately after US-guided MBB. A vasovagal reaction was noted in 4 patients. Procedure level and laterality were not defined in these cases. Transient headache was noted in 2 patients. A small superficial hematoma was noted in 1 patient who underwent unilateral L4 and L5 MBB.

#### 3.4. Ultrasound-guided intra-articular facet joint injections

#### 3.4.1. Technique for performing ultrasound-guided facet joint injections

The included studies describe L1-2, L2-3, L3-4, L4-5, and L5-S1 FJI with varying laterality and injectate volumes as detailed in Table 1. Eight studies described a sagittal view to determine the spinal level followed by a transverse view to identify the target facet joint. One study described using both longitudinal and transverse views to identify the target with injection performed in-plane in a caudal to cranial trajectory. One study described confirmation of intra-articular injection with US but did not describe the particular views that were used. Eight studies described an in-plane approach, and 1 case report described an out-of-plane approach.

FJI, facet joint injection; MBB, medial branch block; US, ultrasound.

![Figure 2. Risk difference forest plots for ultrasound-guided medial branch blocks confirmed by fluoroscopy with and without contrast.](image-url)
et al.19 measured the time to complete bilateral L2-3, L3-4, L4-5, CT control images.16 The other study reported a time of 206 seconds (SD 27 seconds) to perform a single-level FJI.51 Ha et al.19 measured the time to complete bilateral L2-3, L3-4, L4-5, and L5-S1 FJI, with no significant difference in procedure time observed between the US-guided (265 seconds) and fluoroscopy groups (247 seconds).19 Yun et al.55 measured time to complete multiple-level FJI.55 In this study, 25 patients underwent US-guided L4-5 and L5-S1 FJI for a total of 81 injections, while 32 patients underwent fluoroscopically guided L4-5 and L5-S1 FJI for a total of 104 injections. The procedure time in the US-guided group (248.7 seconds, SD 5.9) was shorter than that in the fluoroscopy group (247.8 seconds, SD 5.9) (P = 0.06).13 Notably, in this study, the time recorded for US-guided FJI confirmed using CT, and no heterogeneity was identified (I² = 0%).

### 3.4.4. Procedure time for ultrasound-guided facet joint injections

Two studies reported the procedure time for performing a single intra-articular FJI at L3-4, L4-5, and L5-S1.16,51 One of these studies found a nonsignificant difference for the US-guided group (14.3 minutes, SD 6.6) compared with the CT-guided group (22.3 minutes, SD 6.3).16 Notably, in this study, the time recorded for the US-guided group also included the time expended obtaining CT control images.16 The other study reported a time of 206 seconds (SD 27 seconds) to perform a single-level FJI.51 Ha et al.19 measured the time to complete bilateral L2-3, L3-4, L4-5, and L5-S1 FJI, with no significant difference in procedure time observed between the US-guided (265 seconds) and fluoroscopy groups (247 seconds).19 Yun et al.55 measured time to complete multiple-level FJI.55 In this study, 25 patients underwent US-guided L4-5 and L5-S1 FJI for a total of 81 injections, while 32 patients underwent fluoroscopically guided L4-5 and L5-S1 FJI for a total of 104 injections. The procedure time in the US-guided group (263.4 seconds, SD 6.5) was significantly longer compared with the fluoroscopy group (248.7 seconds, SD 5.9, P = 0.023).55 In the study by Constantinescu et al.,9 which did not have a comparison group, the total US-guided procedure time ranged between 20 and 30 minutes. The number and levels of the injections were not reported.9 The definition and measurement of procedure time varied across studies.

### 3.4.5. Complications associated with ultrasound-guided intra-articular facet joint injections

Complications were reported in 2 studies. Fluid retention in the upper and lower extremities was reported in 1 patient, although it was unclear whether this patient was in the US-guided or CT-guided group.16 Other details including level of the injection or time course of the symptoms were not reported. In the study by Ha et al.,19 a superficial infection that improved within a few days was reported. Whether antibiotics were administered was not reported. In the same study, an episode of transient lower motor neuron weakness that improved within 1 day was reported.19 The distribution of weakness was not reported. Several minor complications were reported in 4 patients in the US-guided FJI group and 3 patients in the fluoroscopically guided FJI group, but specific details about which complication occurred in each treatment group were not reported.19 These minor complications included aggravation of LBP, paresthesia, headache, brief chest pain, and an allergic reaction. All symptoms attributed to the minor complications resolved within a few hours.19

### 3.5. Grading of evidence

Certainty in evidence was assessed as low to very low primarily because of factors related to risk of bias, inconsistency, and imprecision.18 The complete assessment is presented in Table 3. Imprecision was primarily due to small sample sizes. Indirectness was noted because the image-guided interventions required highly specialized skills that may not be easily translated to health care personnel with less experience.14,16,20,21,25,32,37,40,41,54,55

### 4. Discussion

The key findings of this systematic review include the following: (1) The pooled RD of US-guided MBB confirmed by fluoroscopy with or without contrast was 11%, and no significant group differences were observed; (2) the RD of US-guided FJI confirmed by fluoroscopy with contrast was 7%; and (3) the pooled RD of US-guided FJI confirmed by CT was 13%. The time to complete a single-level US-guided MBB ranged from 2.6 to 5.0 minutes, and a single study reported a significantly shorter procedure time for US-guided MBB compared with fluoroscopic guidance.20 However, the time to complete a single or multilevel US-guided FJI varied widely. Few complications were reported for US-guided, fluoroscopically guided, or CT-guided procedures. Important sources of heterogeneity and bias were identified, and the certainty in evidence was low to very low.

The RD of US-guided MMB and FJI as confirmed by fluoroscopy or CT warrants further consideration. Ultrasound technology is based on the piezoelectric principle, whereby electrical current passing through crystals in the US transducer are converted into pulsed sound waves.1,30,53 These ultrasonic waves are transmitted into the targeted tissues and reflected back to the transducer.1,53 High frequency transducers with shorter pulse length yield a higher resolution image. However, resolution is substantially limited when visualizing deeper structures because of attenuation of sound waves through the intervening tissues.1,27,45,46 Depth gain compensation can correct for the loss of acoustic energy through attenuation,36,43 but for deeper structures, depth gain compensation is

- **Quality Assessment**
  - **Certainty in outcomes**: The quality of evidence is graded as high, moderate, low, or very low based on the GRADE system.
  - **Risk of bias**: The risk of bias is assessed for each study.
  - **Publication bias**: The risk of publication bias is evaluated.

- **Procedure Time**: The time required for each procedure was considered. Imprecision because of relatively small sample sizes, some inconsistency from lack of priori statistics, some concern of indirectness because of a specialized skill set required to perform the procedure that may not be widely available.

- **Facet Joint injection**: Imprecision because of relatively small sample sizes, high inconsistency from lack of priori statistics, some concern of indirectness because of a specialized skill set required to perform the procedure that may not be widely available.

- **Nerve blocks for regional anesthesia**: Imprecision because of relatively small sample sizes, high inconsistency from lack of priori statistics, some concern of indirectness because of a specialized skill set required to perform the procedure that may not be widely available.

- **Wu et al.,52**: Imprecision because of relatively small sample sizes, high inconsistency from lack of priori statistics, some concern of indirectness because of a specialized skill set required to perform the procedure that may not be widely available.

Despite the lower accuracy of US-guided needle placement, a previous meta-analysis reported the effectiveness of US-guided FJI were comparable with fluoroscopy-guided and CT-guided FJI.52 In this study, immediate postprocedural outcomes were assessed including pain scores, Modified Oswestry Disability (MOD) scores, and procedure time. Inclusion criteria included randomized and nonrandomized trials. The meta-analysis involved 2 fluoroscopy-guided trials19,55 and 1 CT-guided trial61; these 3 trials were included in our systematic review. In the meta-analysis, the weighted mean difference in pain scores, MOD scores, and procedure time did not differ significantly between the US-guided group and the combined fluoroscopy-guided and CT-guided group. However, high levels of statistical heterogeneity were identified for the pain score and procedure time analyses. No statistical heterogeneity was identified for the MOD analysis, but this comparison only included the 2 fluoroscopy trials.19,55 The findings of this systematic review and meta-analysis extend the findings of the meta-analysis of Wu et al.52 by including trials of US-guided MBB and reporting the RD of inaccurate needle placement. The findings of this review suggest that although the immediate postprocedural pain scores of US-guided FJI were similar to conventional imaging modalities, the risk of inaccurate needle placement could have deleterious effects on the diagnostic accuracy of MBB.

The findings of this systematic review have important implications for research and clinical practice. First, in a summary by Cohen et al.,7 the false-positive rate of fluoroscopically guided MBBs based on placebo-controlled blocks in randomized trials varied from 16% to 30%.8,38,39,42 The false-negative rate may be magnified by imaging modalities that miss the target nerve or cannot reliably detect intravascular uptake.11 The findings of this meta-analysis suggest that US-guided MBB could further impede the ability to accurately identify patients for radiofrequency denervation. However, use of US may be indicated in austere environments or select clinical scenarios where avoiding radiation exposure is a key outcome. The use of US may also be considered when diagnostic accuracy is a secondary concern. For example, as suggested by the findings of the meta-analysis of Wu et al.,52 the therapeutic effects of US-guided FJI may not be affected by inaccurate needle placement; thus, US may be an acceptable imaging modality for these injections. Further research using cadaver dissection models and prospective clinical trials are needed to drive development of techniques aimed at reducing the risk and understanding the clinical effects of incorrectly placed needles. Second, in the study by Rauch et al. that involved adults with a BMI >30 undergoing US-guided MBB, the RD was 38%. This finding is consistent with numerous studies where BMI >30 was associated with an increased risk of failed nerve blocks for regional anesthesia.10,15,34,60

This study has limitations. Details about how the US-guided procedures were performed varied between studies which could have influenced the findings of this systematic review. Training in fluoroscopically guided spine procedures is more extensive than US training. As a result, the outcomes of studies conducted by practitioners with expertise in performing US-guided procedures may not be generalizable to the general population of pain specialty physicians. Potential variations in how fluoroscopy was
used without contrast to confirm needle placement could have affected the study findings. More specifically, no significant RD was observed for the US and fluoroscopy without contrast comparison (Fig. 2). The lack of significance could be due, in part, to high levels of heterogeneity which could be related to undefined variations in how fluoroscopy was used without contrast to confirm needle placement.

In conclusion, the risk of incorrect needle placement associated with US-guided MMB and FJI is high when needle position is confirmed using fluoroscopy or CT (Fig. 4). The technical limitations of US and individual patient characteristics, particularly elevated BMI, could be important determinants of incorrect needle placement associated with US-guided MBB and FJI. Further research is needed to identify optimal procedural techniques aimed at reducing the risk of incorrect needle placement for US-guided facet interventions.
