Inhibition of cyclin dependent kinase 9 by dinaciclib suppresses cyclin B1 expression and tumor growth in triple negative breast cancer

SUPPLEMENTARY FIGURE

**Supplementary Figure S1:** Dinaciclib induced very modest apoptosis in ER+ breast cancer cell lines. A. FACS analysis of ER+ breast cancer cells (MCF7 and T47D) treated with dinaciclib for 24 hours. Percentage of apoptosis (the ratio of Annexin-V and PI-positive cells) was then calculated. Data are presented as average percentage of apoptotic cells ± SEM from 2 experiments. B. Western blot analysis of apoptosis associated proteins after dinaciclib treatment for 4 and 24 hours.
