Abstract
Copper (Cu) is an essential micronutrient for all aerobic forms of life. Its oxidation states (Cu+/Cu2+) make this metal an important cofactor of enzymes catalyzing redox reactions in essential biological processes. In gram-negative bacteria, Cu uptake is an unexplored component of a finely regulated trafficking network, mediated by protein–protein interactions that deliver Cu to target proteins and efflux surplus metal to avoid toxicity. *Rhizobium etli* CFN42 is a facultative symbiotic diazotroph that must ensure its appropriate Cu supply for living either free in the soil or as an intracellular symbiont of leguminous plants. In crop fields, rhizobia have to contend with copper-based fungicides. A detailed deletion analysis of the pRet42e (505 kb) plasmid from an *R. etli* mutant with enhanced CuCl2 tolerance led us to the identification of the ropAe gene, predicted to encode an outer membrane protein (OMP) with a β–barrel channel structure that may be involved in Cu transport. In support of this hypothesis, the functional characterization of ropAe revealed that: (I) gene disruption increased copper tolerance of the mutant, and its complementation with the wild-type gene restored its wild-type copper sensitivity; (II) the ropAe gene maintains a low basal transcription level in cop-per overload, but is upregulated when copper is scarce; (III) disruption of ropAe in an actP (copA) mutant background, defective in copper efflux, partially reduced its copper sensitivity phenotype. Finally, BLASTP comparisons and a maximum likelihood phylogenetic analysis highlighted the diversification of four RopA paralogs in members of the *Rhizobiaceae* family. Orthologs of RopAe are highly conserved in the *Rhizobiales* order, poorly conserved in other alpha proteobacteria and phylogenetically unrelated to characterized porins involved in Cu or Mn uptake.

copper homeostasis, copper uptake, porins, *Rhizobium*, RopA

1 INTRODUCTION

Copper (Cu) is an essential trace element for aerobic organisms of the three domains of life. Cu can exist as an oxidized cupric ion (Cu2+) or as reduced cuprous ion (Cu+). The capacity of copper to alternate between these two oxidation states, (Cu+/Cu2+), makes this metal the ideal cofactor of key enzymes catalyzing redox reactions in vital biological processes, such as respiration, free radical detoxification, the methane cycle, photosynthesis, the carbon cycle, and the nitrogen cycle (Festa & Thiele, 2011; Rubino & Franz, 2012). Cells have...
to maintain intracellular copper in trace concentration; otherwise \( \text{Cu}^+ \) can displace iron from iron-sulfur clusters of metalloproteins, resulting in their inappropriate structure and function. In addition, free iron and \( \text{Cu}^+ \) may cause hydrogen peroxide to generate an increase at the concentration of hydroxyl radicals by a Fenton type reaction which can damage proteins, lipids, and nucleic acids (Macomber & Imlay, 2009).

As copper is essential for life on earth, it is important to understand how cells fulfill their copper requirements and how trace concentrations are maintained to avoid toxicity.

Although the eukaryotic copper uptake system is well-documented (Boal & Rosenzweig, 2009), little information is available about how prokaryotic cells import this metal.

The role of outer membrane proteins (OMP) in \( \text{Cu}^+/\text{Cu}^{2+} \) acquisition was first suggested by Lutkenhaus (1977) who reported the isolation of copper-resistant mutants, in *Escherichia coli B/r*; these appeared with a frequency of \( 10^{-5} \) in minimal medium plates with 20 \( \mu \text{mol/L} \) \( \text{CuSO}_4 \). This phenotype was associated with the absence of outer membrane protein b (OmpC according to Lugtenberg and Van Alphen’s nomenclature published in 1983) (Lugtenberg & Van Alphen, 1983) determined by membrane preparation and gel electrophoresis. Fifteen years later, Lutkenhaus’ hypothesis was contradicted by studies with well-characterized *E. coli B/r* isogenic OmpC mutants which maintained the same level of copper and silver resistance as the parental strain (Bavoil, Nikaido, & von Meyenburg, 1977; Li, Nikaido, & Williams, 1997).

In *Mycobacterium smegmatis* the uptake of nutrients and beta-lactam antibiotics is mediated by the MspA, MspB, MspC, and MspD porins (Danilchanka, Pavlenok, & Niederweis, 2008; Stephan et al., 2005). Their role in copper transport was experimentally assayed in *Mycobacterium smegmatis* porin-deleted mutants which grew poorly under trace concentrations of \( \text{CuSO}_4 \) and simultaneously increased their copper tolerance when exposed to \( \text{CuSO}_4 \) overload (Speer et al., 2013).

The potential role of multiple porins in the uptake of copper has also been suggested by the transcriptional profiles of copper-adapted cells of *Pseudomonas aeruginosa*. This study revealed that at least eight genes coding for different putative porins were downregulated in cells of *Rhizobium etli* (Cubillas et al., 2013, 2014), an \( \alpha \)-proteobacterium belonging to the *Rhizobiales* order that can live as a saprophyte in the rhizosphere of *Phaseolus vulgaris* plants or as a nitrogen fixer in symbiosis with the roots of *P. vulgaris* plants (Segovia, Young, & Martínez-Romero, 1993). Its 6.5 Mb genome is partitioned in one circular chromosome and six plasmids (Gonzalez et al., 2006). The contribution of the *R. etli* pRet42e plasmid to ion balance is due to the presence of NpA, a member of the cation diffusion facilitator family (CDF) required to deal with high nickel concentrations, and the \( P_{18} \cdot \text{ATPase, ActP,} \) a copper efflux pump that confers copper resistance (Landeta et al., 2011).

In this study we report that an isogenic mutant of *R. etli* CFN42, named CFNX185, which lacks 200 kb of its 505–kb plasmid pRet42e, is more tolerant to \( \text{CuCl}_2 \) than the wild-type strain. Further analysis of pRet42e led us to the identification and characterization of the ropAe gene, coding for a putative outer membrane protein (OMP) whose absence increased copper resistance. The enhanced copper resistance phenotype observed in a double actP– ropAe– mutant suggests that disruption of ropAe reduces the intracellular copper supply, alleviating the copper toxicity observed in the actP single mutant that is defective in its copper efflux. Bioinformatic predictions, genetic experiments and transcriptional analyses allowed us to propose that a basal transcription level of ropAe facilitates copper transport across the outer membrane. However, under copper limitation, ropAe increased its transcription level, suggesting that it may play an important role in ensuring copper supply when the bacterium faces copper scarcity.

A phylogenetic analysis revealed that RopAe belongs to the Porin_2 (PF02530) family and that it is distant from MspA, MspB, and MspC porins in *M. smegmatis*, from OmpC of *E. coli* (Li et al., 1997), from MnoP (bbr0095) of *Bradyrhizobium japonicum* (Hohle, Franck, Stacey, & O’Brien, 2011), and from the copper-regulated porins of *Pseudomonas aeruginosa* belonging to the OprD family (Teitzel et al., 2006). Three homologs of RopAe were found encoded in the chromosome of *R. etli* CFN42. The four RopA porin-like transporters belong to different monophyletic groups suggesting a functional divergence among them.

## 2 | EXPERIMENTAL

### 2.1 | Bacterial strains, media, and growth conditions

The characteristics of the bacterial strains and plasmids used in this study are listed in Table S1. Bacterial growth was started from glycerol stocks (20% and stored at \(-70^\circ\text{C}\)) propagated in rich PY medium containing 5 g/L peptone, 3 g/L yeast extract, and 15 g/L agar. After sterilization, 10 mL/0.7 ml/L \( \text{CaCl}_2 \) was added. Minimal medium (Mm) was prepared from three solutions (A, B, C) and sterilized separately. Solution A contained 1.620 g/L sodium succinate hexahydrate as a carbon source, 0.534 g/L \( \text{NH}_4\text{Cl} \) as a nitrogen source, 0.219 g/L \( \text{K}_2\text{HPO}_4 \), and 0.1 g/L \( \text{MgSO}_4 \). The pH of this solution was adjusted to 6.8 before sterilization in autoclave. Solution B contained filter sterilized 0.025 g/5 ml \( \text{FeCl}_2\text{H}_2\text{O} \) and solution C contained 0.7 mol/L \( \text{CaCl}_2\text{H}_2\text{O} \) (autoclaved). A quantity of 1 ml of B solution and 2 ml of C solution were added to 1 L of A solution.

Antibiotics for *R. etli* were added at the following concentrations (\( \mu \text{g/ml} \)): nalidixic acid, 20; streptomycin, 100; gentamicin, 15; and tetracycline, 3. For *E. coli* the antibiotic concentrations were (\( \mu \text{g/ml} \): kanamycin, 30; gentamicin and tetracycline 10.

### 2.2 | Metal sensitivity assay

Metal sensitivity was determined with a plate assay using square Petri dishes with a grid as follows: 50 mmol/L stock solutions of Cu, Ni, Co, Zn, and Cd, 500 mM Fe, and 45 mM chloride salts (Sigma-Aldrich, St Louis, MO) were prepared in Milli-Q water, filter sterilized and added at increasing concentrations to solid (1.5% wt/vol agar) Mm. The *R. etli* overnight cultures were adjusted to \( \text{OD}_{620} = 0.7 \), washed twice with
10 mM of MgSO₄, serially diluted (10⁻¹ – 10⁻⁶) and spotted (20 μl) on solid Mn supplemented with or without metal ions. Growth was recorded after 5 days of incubation at 30°C. The total inhibitory concentration of copper for wild-type R. etli CFN42 was 20 μmol/L. The Minimal Inhibitory Concentrations (MICs) of metals able to reduce, in at least one log-unit, the growth (CFU) were previously determined (Cubillas et al., 2013) as follows: 100 μmol/L Ni, 100 μmol/L Co, 200 μmol/L Zn, 100 μmol/L Cu, 2.5 mmol/L Fe, and 30 mmol/L Mn.

2.3 | DNA manipulation

Cloning, restriction digest, ligation, transformation, Southern blotting, and hybridization were performed according to standard protocols (Sambrook, Fritsch, & Maniatis, 1989).

2.4 | Generation of site-specific deletions

Deletions of pRet42e plasmid were obtained using the Cre/loxP system as previously described (Landeta et al., 2011). Briefly, the region to be eliminated was flanked, in direct orientation, by loxP sites present in pVEX1311 plasmid (Ayres, Thomson, Merino, Balderes, & Figurski, 1993) and in pLC20R (Marsh, Erle, & Wykes, 1984). These suicide vectors, containing a PCR fragment (≥300 bp) of DNA sequences flanking the region to be eliminated were introduced by conjugation into R. etli CFN42. Single crossover recombination mediates the plasmids’ co-integration at the target sequences. The Cre recombinase, introduced by conjugation, mediated the in vivo recombination of both loxP sites and the excision of the target DNA. Plasmid deletions were validated by changes in their electrophoretic mobility using a modification of Eckhardt gel electrophoresis procedure (Hynes & McGregor, 1990) that consists of a gentle lysis, running the SDS solution backwards, followed by the loading of wells with cells and starting the lysis, running the SDS solution forwards. The second validation was done by the absence of amplicons, using the total genome of the deleted strain as PCR template.

2.5 | Site-directed vector integration mutagenesis and mutant complementation

A 400 bp internal fragment of the target genes were amplified by PCR (see Table S2 for primers) and cloned into pK18mob Km′ suicide vector (Schäfer et al., 1994). Plasmids were introduced into R. etli CFN42 by conjugation and mutants with vector integration by single-crossover were selected as Km′ clones. Vector integration in the target gene was verified by Southern blot, using the internal 400 bp of the target gene, amplified by PCR as the probe.

To complement the phenotype of the ropAe mutant, PCR-amplified fragments containing the complete ropAe gene or its ropAch1, ropAch2, and ropAch3 paralogs were cloned into the broad-host-range pBBRMC5-5 plasmid (Kovach et al., 1995) or in its derived expression, pSRK vector (Khan, Gaines, Roop, & Farrand, 2008), and introduced into ropAe mutant by conjugation (Table S1).

2.6 | Construction of a ropAe/actP double mutant

A 1.3 kb PCR-amplified BamHI–XhoI fragment of the actP gene was cloned into pBluescript II SK(+) vector. The HindIII–HindIII ΩSp interposon (Fellay, Frey, & Krisch, 1987) was inserted into the sole HindIII restriction site of PCR-amplified actP, located 900 bp upstream of the TAG stop codon. The BamHI–XhoI fragment containing the actP::ΩSp was subcloned into pJQ200 SK (Quandt & Hynes, 1993) and then introduced by conjugation into wild type R. etli CFN42 using E. coli S17-1 (Simon, 1984) as donor. The wild-type actP gene was replaced by the actP::ΩSp by double homologous recombination in most of the transconjugants grown in the presence of sucrose 12.5%. The gene replacement was verified by Southern blot using Redyprime kit for labeling with [α-³²P] the DNA fragment used as probe. To construct the double mutant ropAe::pK18mob/actP::ΩSp, the wild-type ropAe was disrupted by site-directed vector integration of the pK18mob plasmid in the actP::ΩSp mutant background as described above.

2.7 | Cu-dependent transcriptional response of ropAe measured by qRT-PCR

To determine the effect of either copper excess or deficiency on ropAe expression, two different experiments were performed. For the copper excess condition, PY cultures (20 ml, OD₆₂₀ nm = 0.65–0.75) of wt R. etli were exposed for 30 min to 0.5 mmol/L CuCl₂. For the copper deprivation treatment, wt R. etli was grown overnight in 20 ml of PY with or without 2 mmol/L of the membrane impermeable Cu⁺/Cu²⁺ chelator bathocuproine disulfonic acid disodium salt (BCDS, Sigma) (Ding, Xie, & Kang, 2011). These were used to extract the mRNA using the TriPure isolation reagent (Roche). The total RNA (DNA free, 1 μg) was reverse transcribed to cDNA using ReverAid H minus FirstStrand cDNA Synthesis (Fermentas). Quantitative real-time PCR was performed on StepOnePlus (Applied Biosystems) using Maxima Syber Green/ROX qPCR master Mix (Fermentas) and 1 μg of cDNA as template. The ropAe, actP and hisCd genes were amplified by using the primers listed in Table S2. Their expression levels in the presence of CuCl₂ or CuCl₂ plus the BCDS Cu⁺/Cu²⁺ chelator were normalized to the expression level of housekeeping hisCd gene (Salazar et al., 2010). The data represent averages of four independent experiments with three technical replicates each. The fold change in gene expression was calculated using the ΔΔCt method (Schmittgen & Livak, 2008).

2.8 | Bioinformatic prediction of subcellular localization of RopAe

The localization of RopAe was analyzed with two different predictors of subcellular localization with high accuracy for OMP (Bhasin, Garg, & Raghava, 2005). The multimodular PSORT-B (Gardy et al., 2003) examines the query sequence for the presence of 12 different characteristics, such as amino acid composition, similarity to proteins of known localization, signal peptide, alpha helices, motifs, etc. (http://www.psort.org/). The second predictor was CELLO (Yu, Lin, & Hwang, 2004) which uses a single analytical module, a support vector machine based on n-peptide composition (http://
2.9 | Searching for RopAe homologs in protein databases and bacterial genomics

Protein Blast program (BlastP) at NCBI with default settings, was used to search databases or bacterial genomes for RopAe homologs. BlastP was also used to align two sequences and estimate identity (%), similarity (%), query cover (%), and E value.

2.10 | Phylogenetic analysis of the Porin_2 family (PF02530)

According to Pfam, the Porin_2 (PF02530) family includes 263 OMP from alpha proteobacteria. To assess the number of rhizobial porins contained in this family, as well as their taxonomic distribution and diversity, the porins of members of the Rhizobiales order were downloaded, filtering from other α-proteobacteria with the species distribution sequence search tool included in pfam 30.0. A total of 145 OMP homologs belonging to 35 species of Rhizobiales, as well as OmpC (a nonspecific porin) of E. coli, MnoP (a manganese transporter) of B. japonicum (Hohle et al., 2011), MspA, MspB, MspC, and MspD porins of M. smegmatis (Speer et al., 2013) comprised the data set (Table S4) and were aligned against the HMMER profile using hmmalign. The most conserved regions shared among the OMPs were obtained from the alignment of putative RopAe with the HMMER profile. The resultant data set, containing 127 OMPs (Table S4), was used to infer the evolutionary relationships among the rhizobial OMPs belonging to the Porin_2 family (PF02530) relative to the other characterized porins. Due to the low bootstrap values observed in the 127 sequences phylogeny (Figure S2), we decided to select the clades where the RopAe proteins and their closest homologs were located and we run the analysis again including the characterized proteins. The resulting phylogeny (Figure 6) has higher bootstrap values that support the conclusions. The ML-phylogenetic analysis was performed under the LG+G+I model using amino acid alignment. The phylogeny was built using a parallel P threads-based version of RAxML v8.2.4, because this software supports SSE3 vector instructions (Stamatakis, 2014). The ML-search started with 100 random seed trees and the best tree was selected. Rapid bootstrapping was used to assess the branch support (Stamatakis, 2014). The number of necessary replicates was estimated at 100 using the extended majority rule criterion (Pattengale, Aberer, Swenson, Stamatakis, & Moret, 2011).

3 | RESULTS

3.1 | Characterization of an R. etli mutant with increased copper tolerance

As a result of previous research conducted to analyze the functional contribution of the six R. etli CFN42 plasmids to contend with stress conditions, a collection of derivative mutants was constructed. The derivatives lack each of the following plasmids: pRet42a, pRet42b, pRet42c, pRet42d, and pRet42f, or a 200 Kb fragment of plasmid pRet42e (Brom et al., 1992). We assessed the toxic effect of Cu and other metals on these mutants by determining their growth capacity, as described in Materials and Methods, in minimal medium agar plates supplemented with increased concentrations of CuCl₂ (0–25 μmol/L). The assays revealed that 20 μmol/L CuCl₂ totally inhibited the growth of the parental strain (CFN42) (Figure 1) as well as that of the other plasmid-cured strains (data not shown). In contrast, the derivative lacking 200 kb of pRet42e (strain CFNX185) showed full growth on 20 μmol/L CuCl₂ (Figure 1). To identify the gene(s) responsible for the tolerance phenotype, consecutive small site-directed deletions were constructed using the Cre/loxP system (see Materials and Methods) (Landeta et al., 2011). The increased copper tolerance observed in CFNX185 was also observed in strains with deletions peΔ10 (124 kb) and peΔ20 (60 kb); whereas deletion peΔ21 (41 kb) showed a wild-type phenotype (Figure 1). This indicated that the gene(s) involved in copper resistance must be localized on a 19 kb region still present in plasmid peΔ21 (Figure 1, white triangle). The organization of the

FIGURE 1 Identification of ropAe gene through the analysis of the copper-resistance phenotype of wt R. etli CFN42 and its isogenic mutants harboring spontaneous (CFNX185) or engineered (Δ11 to Δ21) deletions of plasmid p42e (see Cu sensitivity assay in methods). R. etli CFN42 is unable to grow in minimal medium containing 20 μmol/L of CuCl₂. Its isogenic mutant, R. etli CFNX185, lacking 200-Kb of plasmid p42e, acquired the ability to grow in this medium. The copper-resistance phenotype of mutants harboring sequential deletions of plasmid p42e (peΔ11 to peΔ21), covering the 200-kb region lost in CFNX185, indicates that the absence of a 19-kb fragment increases copper resistance. Four transporter-coding genes contained in this fragment were disrupted by site-directed vector integration (open and filled triangles). Only the mutation of ropAe (RHE_PEO0260) increased Cu resistance (open triangle). Images are representative of five independent experiments.
genes localized in this fragment and their predicted functions are listed in Table S5. A schematic representation of some of these genes is shown at the bottom of Figure 1, highlighting the presence of a 4,080 bp four-gene cluster, RHE_PE00245 to RHE_PE00248, encoding a putative sugar ABC transport system, a sulphate uptake ABC transport system formed by five proteins (RHE_PE00259 to RHE_PE00256), and a putative OMP (RHE_PE00260, 1,017 bp) encoded close to a three-gene cluster, which is part of the KdpA–KdpE (RHE_PE00266–RHE_PE00262) potassium transporting system.

3.2 | Disruption of ropAe increases copper tolerance in *R. etli* CFN42

The analysis described above indicates that 10 out of 19 proteins encoded in the 19 Kb fragment of pRet42e might be involved in transport of small molecules and cations. To explain the copper resistance phenotype, we hypothesized that these proteins may participate in the uptake of divalent cations, including copper. Under a copper overload the absence of these Cu importers would reduce the transport of metal, resulting in a Cu resistance phenotype. To test this hypothesis, we constructed mutants in genes RHE_PE00245 and RHE_PE00259, coding for solute binding proteins, annotated as components of the sugar and sulfate ABC transport systems, respectively; also in gene RHE_PE00260, coding for an uncharacterized OMP, and in RHE_PE00263, coding for a putative two-component sensor histidine kinase, belonging to the putative potassium transport system (kdpA–kdpE) (Figure 1 and Table S5). The copper resistance phenotype of these mutants was assessed by determining growth of 10-fold serial dilutions on minimal medium plates supplemented with 20 μmol/L CuCl$_2$. The only mutation that produced an increased Cu resistance phenotype was that in the RHE_PE00260 gene coding for a putative OMP labeled as ropAe. The complementation of the ropAe$^{-}$ mutant with the wild-type gene, led to recovery of wild-type levels of Cu sensitivity (Figure 2). These results indicate that the product of ropAe gene increases copper sensitivity.

3.3 | Loss of *R. etli* ropAe gene does not enhance Mn$^{2+}$, Cd$^{2+}$, Ni$^{2+}$, Fe$^{2+}$, Co$^{2+}$, and Zn$^{2+}$ resistance

According to the Transport Classification Data Base (Saier et al., 2016), most of the 16-strand porins are classified as general or non-specific transporters that allow the diffusion of hydrophilic substrates. To determine if RopAe mediates the sensibility to other divalent metal cations, *R. etli* and its isogenic ropAe mutant were grown on plates containing minimal inhibitory concentrations of Mn$^{2+}$, Cd$^{2+}$, Ni$^{2+}$, Fe$^{2+}$, Co$^{2+}$, and Zn$^{2+}$ (previously determined for the wild-type strain). We found that the inhibitory effect of all these metals was similar for both strains (Figure S1).

3.4 | The disruption of ropAe gene partially reverts the copper sensitivity phenotype of an *R. etli* actP mutant defective in copper detoxification

In the genome sequence of *R. etli* CFN42, ORF RHE_PE00007 is annotated as an actP homolog (ropA in other bacteria), coding for a P$_{1B-1}$-copper-transporting ATPase protein, predicted to be located in the inner membrane, whose function is to pump copper out of the cytoplasm (http://genomeannotation.jsp/rhizobieti/genes/RHE_PE00007). Landeta et al. (2011) showed that actP disruption reduced the copper resistance of this bacterium, suggesting a deficiency in copper efflux. To get insights into the putative porin-like role of ropAe in the uptake of copper, we hypothesized that an actP::ΩSp mutant, defective in cytoplasmic copper detoxification, should be rescued from a toxic copper overload (7.5 μmol/L CuCl$_2$) if the putative entrance of copper is “closed” by mutation of the ropAe gene (ropAe::pK18 mob Km). As predicted, the actP::ΩSp/ropAe::pK18mob double mutant increased its copper tolerance in three orders of magnitude, compared to the single actP mutant (Figure 3). This result, together with the increased resistance to copper of the ropAe mutant, the Cu sensitivity of the complemented ropAe mutant, as well as the in silico structural analysis, reinforces the hypothesis that RopAe facilitates copper uptake.

3.5 | The transcription of ropAe is upregulated under copper limiting conditions

To determine the effect of copper on the transcription of ropAe, its expression was analyzed by qRT-PCR in the exponential growth phase (OD$_{620nm}$ = 0.7) of cultures exposed or unexposed for 30 min to a non-inhibitory overload of 0.5 mmol/L CuCl$_2$. These induction conditions were validated by measuring the copper-inducible actP gene of *R. etli* CFN42 that encodes a putative P$_{1B-1}$-Cu$^{2+}$-ATPase efflux pump (Landeta et al., 2011).

From studies in other bacterial models, such as *Agrobacterium fabrum* CS8 (formerly *A. tumefaciens* CS8), a close relative of *R. etli*, we assumed that the transcription of *R. etli* actP gene is activated by the

**FIGURE 2**  The disruption of ropAe increases copper resistance. The comparison of the growth presented by wt *R. etli* CFN42, the ropAe mutant (ropAe$^{-}$), the mutant complemented with the empty vector (ropAe$^{-}$/pBBR) and with the ropAe gene (ropAe$^{-}$/ropAe) were assessed with the copper sensitivity plate assay described in the Methods section. Images are representative of five independent experiments.
monovalent copper-dependent protein CueR that binds to a regulatory region of actP and induces its transcription through a conformational DNA change required for transcriptional activation of actP (Bittner, Kraus, Schäkermann, & Narberhaus, 2017; Nawapan et al., 2009). As expected, the relative expression of the actP gene increased 25-fold after copper treatment (Figure 4). In contrast, no significant difference was found in the expression of ropAe in cultures treated similarly (Figure 4).

There are several examples cited in the literature of upregulation of high-affinity porin-encoding genes at lowmetal concentrations (Hohle & O’Brien, 2009; Patzer & Hantke, 1998; Speer et al., 2013). To determine whether ropAe is induced under copper limitation, its transcription was assessed in overnight cultures of wt R. etli (Hohle & O’Brian, 2009; Patzer & Hantke, 1998; Speer et al., 2013). As can be seen in Figure 4b, the partial growth recovery of the actP−/ropAe− double mutant may be due to a reduction in the influx of Cu⁺ by disruption of the ropAe gene. Images are representative of five independent experiments.

3.6 | The ropAe gene encodes a putative OMP that shares structural characteristics with porins

According to the annotation of the R. etli CFN42 genome, ropAe is an ORF of 1,017 nucleotides, located in plasmid p42e, encoding a 338 amino acid protein annotated as an uncharacterized porin predicted to be located in the outer membrane. This predicted location was reinforced using other bioinformatic tools. First, a BlastP search with default settings indicates that the overall sequence of RopAe is a domain shared with members of the Porin_2 family (porins from the α class of Proteobacteria) and that the OM_ channels a superfamily containing 16–18 beta-stranded barrels. To support its outer membrane localization, RopAe was analyzed with two different predictors of subcellular localization (see Methods section for details) with high accuracy for OMPs (Bhasin et al., 2005; Table S3). The multimodular PSORT-B (Gardy et al., 2003) and the CELLO predictor (Yu et al., 2004) are based on n-peptide composition (http://cello.life.nctu.edu.tw/). Both methods assigned high probability values to the outer membrane localization of RopAe: the PSORT-B probability was 9.3 of 10 as maximum score; the CELLO probability was 4.105 of 5 as maximum score (Table S3).

The closest homologs are putative OMPs mainly encoded in plasmids of other R. etli and R. leguminosarum strains, with identities ranging from 96 to 100% with a query coverage ≥95% (Table S6). The identity of RopAe to homologs present in other members of Rhizobiales fell in a range from 30% to 50%. To learn more about the structure of RopAe and its closest homologs, their amino acid sequences were analyzed with the transmembrane beta-barrel topology prediction BOCTOPUS2 server (Hayat & Elofsson, 2012) (http://boctopus.bioinfo.se/). All of the analyzed putative OMP porins shared 16 transmembrane β-strands distributed from amino acids 58 to 338, which form part of the typical β-barrel structure of porins (Table S6). We used RopAe homologs as queries against the CATH/Gene 3D (v4.1) protein domains database to predict the 3D structure adopted by these putative OMPs (Lam et al., 2016; Sillitoe et al., 2015) (http://www.cathdb.info/). This search revealed that all tested RopAe homologs, including the partially characterized OMP from R. leguminosarum 248
homologs: RHE_CH01349 (RopAch1), RHE_CH02437 (RopAch2), and RHE_CHO3578 (RopAch3) which share 59% and 58% identities respectively with RopAe (Table S7). Although the four putative porin domains (de Maagd et al., 1992), share a porin domain of 266 amino acids present in the outer membrane proteins grouped in the OMP IIIA family. CATH/Gene 3D (v4.1) predicts “transport” as the associated biological process and “outer membrane” as the cellular component (Table S6). We also identified an additional putative porin present in multiple species of Mesorhizobium (NCBI Taxid 3744) that share 31% identity with RopAe. However, CATH/Gene 3D assigned these mesorhizobial porins to the OmpP2 family (Table S6).

3.7 | The plasmid-borne RopAe protein shares structural characteristics with three RopA homologs encoded in the chromosome of R. etli CFN42

As the R. etli genome is characterized by a high level of gene redundancy (Flores et al., 1987) we searched for RopAe homologs through a BLASTP search using RopAe as query against the proteome of R. etli CFN42. This search retrieved three chromosomally encoded RopAe homologs: RHE_CH01349 (RopAch1), RHE_CH02437 (RopAch2) and RHE_CHO3578 (RopAch3) which share 59% and 58% identities respectively with RopAe (Table S7). Although the four putative porins share structural characteristics such as the 16 transmembrane α strands and the predicted 3D model (Table S7), the increase in copper resistance of ropAe mutant could not be complemented with the chromosomally encoded ropA genes present in cis. To get insight into the functional role of RopAch1, RopAch2, and RopAch3 we attempted to obtain mutants by vector integration; however, Southern blot analyses revealed multiple fragments of unexpected sizes suggesting that these mutants contain more than one vector integration (data not shown). This is supported by a pairwise nucleotide sequence alignment that revealed an 80% to 90% identity shared among the three chromosomally encoded ropA genes (Table S8).

Alternatively, the functional redundancy of these genes in copper transport was investigated using a genetic complementation approach. The three chromosomally-encoded ropAch genes and ropAe were cloned into the pSRKGm vector and introduced into the R. etli mutant ropAe::pK18mob by conjugation. The transconjugants harboring ropAch1, ropAch2 or ropAch3 maintained the same copper resistance level as the mutant ropAe::pK18mob. In contrast, the transconjugant ropAe gene was able to reduce the enhanced copper resistance of the ropAe mutant. These data support the hypothesis that RopAe and RopAchs play different roles (Figure 5).

Furthermore, the location of the four ropA homologs in different gene contexts (Table S7) suggests that these genes could be following different evolutionary pathways, as has been observed in genes from other models analyzed with different bioinformatic gene context tools (Dewey, 2011; Martinez-Guerrero, Ciria, Abreu-Googder, Moreno-Hagelsieb, & Merino, 2008; Puggioni et al., 2014; Seret & Baret, 2011). In support of the functional divergence hypothesis and outer membrane protein localization, it was recently reported that two R. etli RopAe paralogs, RopAch1 and RopAch2, were found to be expressed in the exoproteome of this organism when exposed to the plant flavonoid naringenin (Meneses et al., 2017).

3.8 | RopAe defines a new class of porins distantly related to those involved in Mn and Cu uptake

The BlastP search in the nonredundant database for R. etli RopAe homologs also revealed the presence of a conserved domain that spans from amino acid 33 to 322 (E value 1.93e-72) and groups these proteins in the Porin_2 (PF02530) Pfam. This family clusters OMPs from α-proteobacteria that share this domain. The compilation of these data revealed that the presence of multiple RopA porins is a widespread characteristic in the genomes of members of the Rhizobiales. The number of ropA per genome varies from one to nine, with three being the most frequent number of ropA per genome (Table S4).

To understand the evolutionary relationships of RopAe and paralogs in relation to other OMPs involved in metal trafficking, we aligned the rhizobial porins grouped in the Porin_2 (PF02530) family, characterized porins involved in Mn (MnP from B. japonicum) and Cu (MspA−D from M. smegmatis) uptake and the best-studied porin of γ-proteobacteria, OmpC. The P. aeruginosa OprC, OprD, OprE, OprG, and OprN porins, reported to be downregulated in Cu-adapted culture, were excluded from the alignment because they have an e-value higher than the usual cut-off (<1e-3) (Table S8). The maximum likelihood-based phylogeny inferred from the alignment of 127 amino acid sequences of rhizobial porins was used to define major groups of proteins (Figure S2) including non-RopA protein homologs found in rhizobia. A phylogeny containing the closest RopA homologs as well as multiple out-group characterized proteins (Figure 6) clearly shows that rhizobial RopAe homologs belong to a new class of porins distantly related to those known to be involved in Mn and Cu trafficking.
As part of a research project focused on understanding copper trafficking in the facultative diazotroph R. etli CFN42, we searched for mutants with enhanced copper resistance in a collection of R. etli mutants that have lost whole plasmids or fragments of them, both spontaneously or through programmed deletions. Using this approach we identified a plasmid-encoded gene, annotated as ropAe, whose disruption enhanced copper resistance, and we further determined that the wt sensitivity could be recovered upon introduction of the wt ropAe gene. According to the annotation of the genome at NCBI, the ropAe gene (RHE_PE00260) is located in plasmid p42e and encodes a protein of 338 amino acids, identified as a porin outer membrane protein. The presence of a putative domain containing a multi-pass transmembrane protein that forms a pore of passive diffusion across the outer membrane is predicted between amino acids 33 and 332. Based on this information we hypothesized that ropAe encodes a putative OMP involved in copper uptake. In this study we performed bioinformatics, genetics and gene expression analyses to examine this hypothesis.

The OM localization was supported by an in silico analysis of the amino acid sequence using two different predictors with high accuracy for OMPs: PSORT-B and CELLO. Both predictors assigned high probability values for OM localization. The structural characteristics of RopAe, such as the transmembrane beta-barrel topology and the 3D structure adopted by OMPs were well supported using BOCTOPUS2 server and CATH/gene 3D.

We hypothesized that if ropAe encodes a porin-like protein that contributes to the normal supply of copper, we would expect that a ropAe mutant will show alterations in copper-dependent functions due to a reduction in copper availability. In support of this proposal we found that an R. etli CFN42 actP mutant, defective in cytoplasmic detoxification of copper due to a Tn5 disruption of its P12-Cu-transporting ATPase, cannot grow in the presence of 7.5 μmol/L CuCl2. However, the actP/ropAe double mutant partially recovered its growth ability in 7.5 μmol/L CuCl2. The results of our experiments suggest that this is due to a deficiency in copper supplementation produced by the disruption of ropAe. These data need to be corroborated by determining the transport activity of RopAe.

The inhibitory effect of other divalent metal cations was similar for both strains (Figure S1). This result suggests that RopAe does not facilitate the uptake of metals other than copper, or alternatively, that RopAe might mediate a defective uptake for these metals that does not result in toxic levels in the cytoplasm. Otherwise, there could be a functional redundancy among different porins for these metals, as reported for M. smegmatis (Speer et al., 2013). In gram-negative bacteria there is only a study of putative porins which are down-regulated in copper-adapted cultures of P. aeruginosa (Teitzel et al., 2006).

As studies on copper uptake are extremely scarce in prokaryotes, the identification and characterization of proteins involved in the acquisition of this metal are a topic of major interest in the study of copper homeostasis in bacteria. The best characterized bacterial proteins involved in copper acquisition are the MspA porin and its paralogs in M. smegmatis (Speer et al., 2013). In gram-negative bacteria there is only a study of putative porins which are down-regulated in copper-adapted cultures of P. aeruginosa (Teitzel et al., 2006).

4 | DISCUSSION

Figure 6 The putative RopA OMPs of rhizobia define a new family of porins phylogenetically unrelated to already characterized metal uptake porins. A maximum likelihood phylogenetic tree inferred from a subset of 30 proteins analyzed in a larger phylogeny (Figure S2) showed that RopA proteins clearly define a monophyletic clade of proteins distantly related to characterized metal uptake proteins MnpA (Mn) and MspA-D (Cu), supported by bootstrap values ≥90. The diversification of R. etli and R. leguminosarum RopAe and its homologs RopAch, is evinced by its separation into two clades. The copper porins of M. smegmatis, the general porin OmpC of E. coli and the high-affinity Mn2+ importer MnpB of B. japonicum used as outgroups, are distantly related to R. etli porins (Figure S2). The scale bar indicates the expected number of amino acid substitutions per site under the LG + G + f model.
upregulated and the expression of actP is turned off. Low copper conditions were established with the chelator agent BCDS, a charged and membrane impermeable chelator commonly used in studies that require an extracellular copper depletion condition. The BCDS chelates Cu\(^{+}\) but is also known to bind Cu\(^{2+}\), forcing a tetrahedral chelator geometry that facilitates the reduction in Cu\(^{2+}\) to Cu\(^{+}\) (Asahi et al., 2014; Campos et al., 2009; Ding et al., 2011; Labbé et al., 1997). The BLASTP search was restricted to the genome of \textit{R. etli} CFN42 using its own ropAe as query; it revealed the presence of three \textit{ropAe} homologs located in distant regions of the \textit{R. etli} CFN42 chromosome. As none of these homologs substitutes for \textit{ropAe}, we proposed a functional divergence between RopAe and its chromosomally encoded homologs RopAch1, RopAch2, and RopAch3, which is also supported by the phylogenetic analysis that separates the plasmid and chromosomally encoded RopA homologs into two different clades.

A complex evolutionary story of porin-encoding genes is assumed by the presence of gene redundancy in both prokaryotic and mitochondrial genomes. The presence of multiple copies may have an important role in the stress response of the cell, maintaining a function in the case of loss of primary genes (Bay, Hafez, Young, & Court, 2012; Pinne et al., 2006; Saccone et al., 2003). For instance, in \textit{M. smegmatis}, the porin-mediated copper uptake requires the cooperation of redundant porin homologs; a phenotype of increased Cu resistance could only be obtained in double and triple porin mutants (Speer et al., 2013).

All the data described above strongly support the hypothesis that \textit{ropAe} encodes a porin-like protein that facilitates copper diffusion by increasing its expression under low copper concentrations. Future experiments will address the transport properties of RopAe and its role, if any, in symbiosis with \textit{Phaseolus vulgaris} plants in the presence of copper.

ACKNOWLEDGMENTS

We gratefully acknowledge the funding received from UNAM-DGAPA-PAPIIT, grant number IN209815. A. González-Sánchez is a doctoral student of the Programa de Doctorado en Ciencias Biomédicas, Universidad Nacional Autónoma de México (UNAM) and received a fellowship from CONACYT (No. 290161).

The authors are grateful to Laura Cervantes for her skillful technical assistance, María Luisa Tabche (IBT-UNAM) for her valuable help with qRT-PCR experiments and Susana Brom for helpful discussions and for critically reviewing the manuscript.
