Peroxisome-derived lipids regulate adipose thermogenesis by mediating cold-induced mitochondrial fission

Hongsuk Park, … , Katsuhiko Funai, Irfan J. Lodhi

Peroxisomes perform essential functions in lipid metabolism, including fatty acid oxidation and plasmalogen synthesis. Here, we describe a role for peroxisomal lipid metabolism in mitochondrial dynamics in brown and beige adipocytes. Adipose tissue peroxisomal biogenesis was induced in response to cold exposure through activation of the thermogenic coregulator PRDM16. Adipose-specific knockout of the peroxisomal biogenesis factor Pex16 (*Pex16-AKO*) in mice impaired cold tolerance, decreased energy expenditure, and increased diet-induced obesity. Pex16 deficiency blocked cold-induced mitochondrial fission, decreased mitochondrial copy number, and caused mitochondrial dysfunction. Adipose-specific knockout of the peroxisomal β-oxidation enzyme acyl-CoA oxidase 1 (*Acox1-AKO*) was not sufficient to affect adiposity, thermogenesis, or mitochondrial copy number, but knockdown of the plasmalogen synthetic enzyme glyceronephosphate O-acyltransferase (GNPAT) recapitulated the effects of Pex16 inactivation on mitochondrial morphology and function. Plasmalogens are present in mitochondria and decreased with Pex16 inactivation. Dietary supplementation with plasmalogens increased mitochondrial copy number, improved mitochondrial function, and rescued thermogenesis in *Pex16-AKO* mice. These findings support a surprising interaction between peroxisomes and mitochondria regulating mitochondrial dynamics and thermogenesis.

Peroxisomes perform essential functions in lipid metabolism, including fatty acid oxidation and plasmalogen synthesis. Here, we describe a role for peroxisomal lipid metabolism in mitochondrial dynamics in brown and beige adipocytes. Adipose tissue peroxisomal biogenesis was induced in response to cold exposure through activation of the thermogenic coregulator PRDM16. Adipose-specific knockout of the peroxisomal biogenesis factor Pex16 (Pex16-AKO) in mice impaired cold tolerance, decreased energy expenditure, and increased diet-induced obesity. Pex16 deficiency blocked cold-induced mitochondrial fission, decreased mitochondrial copy number, and caused mitochondrial dysfunction. Adipose-specific knockout of the peroxisomal β-oxidation enzyme acyl-CoA oxidase 1 (Acox1-AKO) was not sufficient to affect adiposity, thermogenesis, or mitochondrial copy number, but knockdown of the plasmalogen synthetic enzyme glyceronephosphate O-acyltransferase (GNPAT) recapitulated the effects of Pex16 inactivation on mitochondrial morphology and function. Plasmalogens are present in mitochondria and decreased with Pex16 inactivation. Dietary supplementation with plasmalogens increased mitochondrial copy number, improved mitochondrial function, and rescued thermogenesis in Pex16-AKO mice. These findings support a surprising interaction between peroxisomes and mitochondria regulating mitochondrial dynamics and thermogenesis.

Introduction
Obesity remains a serious global health problem that increases the risk for type 2 diabetes and other diseases, including cardiovascular disease and several forms of cancer. Current pharmacological approaches to treat obesity primarily target energy intake by suppressing appetite or blocking intestinal absorption of fat and are associated with multiple side effects, suggesting a need for alternative approaches. Targeting brown adipose tissue (BAT) function to increase energy expenditure represents one such approach. Unlike white adipose tissue (WAT), which is involved in storing excess energy as fat that can be mobilized in times of need, BAT oxidizes chemical energy in food to generate heat through uncoupled respiration in response to β-adrenergic stimulation. In addition to the classical BAT, brown adipocyte–like beige cells appear within subcutaneous WAT in response to prolonged cold exposure. Brown fat and beige fat are enriched in mitochondria and express uncoupling protein 1 (UCP1), a mitochondrial membrane protein that uncouples respiration from ATP synthesis. Because thermogenesis promotes energy expenditure, increasing the activity of brown and beige fat cells may be an attractive strategy for treating obesity.

Like mitochondria, peroxisomes are abundantly present in BAT (1). As multifunctional organelles, peroxisomes are involved in a variety of metabolic functions, including β-oxidation of very long chain fatty acids (VLCFAs), α-oxidation of methyl-branched fatty acids, synthesis of ether lipids and bile acids, and production and decomposition of ROS (2).

Peroxisomes are generated through growth and division of existing peroxisomes or through de novo peroxisomal biogenesis. Recent studies suggest that de novo formation of peroxisomes requires fusion of a pre-peroxisomal vesicle derived from the ER with a vesicle derived from the mitochondria (3). Assembly of functional peroxisomes involves proteins called peroxins that are required for various aspects of peroxisomal biogenesis (4). Mutations in these factors result in peroxisomal biogenesis disorders in the Zellweger spectrum, devastating conditions characterized by a host of abnormalities (5). Three of these factors (Pex3, Pex16, and Pex19) are critical for assembly of the peroxisomal membrane and import of peroxisomal membrane proteins (PMPs). Humans with null mutations of these peroxins lack peroxisomes. Pex19 is a chaperone and import receptor for newly synthesized PMPs (6). Pex16 buds from the ER in a pre-peroxisomal vesicle and fuses with a pre-peroxisomal vesicle containing Pex3 (and Pex14) at the mitochondrial surface, resulting in a peroxisome that can import its matrix proteins and proliferate through growth and division (3). Peroxisomal matrix proteins are translated on free ribosomes in the cytoplasm prior to their import. These proteins have specific peroxisomal targeting sequences (PTSs) located at either the car-
bovyl (PTSI) or amino (PTS2) terminus (7, 8). The import receptor for PTS1-containing peroxisomal matrix proteins is Pex5 (9). PTS2-containing peroxisomal matrix proteins require Pex7 for their import into the peroxisome (10).

Cold exposure has been shown to increase peroxisomes and their enzyme activities in BAT (11–13). However, the physiological significance of peroxisomes in BAT is poorly understood. Efforts to understand the role of peroxisomes in adipose tissue using mice with knockout of Pex5 driven by α2C-Cre were impeded by the nonspecificity of the Cre driver, which deleted the gene in multiple other tissues besides adipose tissue, including the brain and the peripheral nervous system, resulting in a complicated phenotype related to compromised muscle function (14). Thus, whether peroxisomes are required for BAT-mediated (nonshivering) thermogenesis and the mechanism through which they might regulate this process remain unknown.

Using a model of adipose-specific peroxisome deficiency generated through adiponectin-Cre-mediated knockout of Pex16, here we demonstrate that peroxisomes are critical for adipose tissue thermogenesis. Mechanistically, our results uncover a role for peroxisomes in division of mitochondria in brown and beige adipocytes.

Results
Peroxisomal biogenesis increases in adipose tissue in response to cold exposure and high-fat feeding. The physiological role of peroxisomes in adipose tissue remains unclear. Thus, we assessed peroxisomal biogenesis genes during differentiation of primary brown and white adipocytes (Supplemental Figure 1; supplemental material available online with this article; https://doi.org/10.1172/JCI120606DS1). Quantitative real-time PCR (qPCR) analysis showed induction of genes involved in peroxisomal biogenesis during both brown and white adipogenesis, with more expression in BAT (Supplemental Figure 1B). Peroxisomal genes were generally expressed at a higher level in brown adipose tissue–mediated thermogenesis than in white adipose tissue (iWAT), and gWAT from mice kept at room temperature or subjected to cold exposure and conducted gene expression analysis in iWAT. Although PRDM16 was dispensable for constitutive peroxisomal biogenesis, its knockout completely blocked the cold-induced increase in peroxisomal biogenesis in iWAT, without affecting the expression of genes involved in lysosomal function, such as Ctsb and Lipa (Figure 1E).

Generation of adipose-specific Pex16-knockout mice. Pex16 is required for peroxisomal biogenesis (20). Immunofluorescence analysis in differentiated BAT SVF cells demonstrated strong colocalization of Pex16 with PMP70, a peroxisomal marker, and not with COX IV, a mitochondrial marker (Supplemental Figure 2). By studying the role of peroxisomes in thermogenesis, we generated Pex16lox/lox mice (Figure 2) and crossed them with adiponectin-Cre mice (18). We maintained 6-week-old PRDM16-lox/lox animals (17) with adiponectin-Cre mice (18). We maintained 6-week-old PRDM16-lox/lox and control mice at room temperature or subjected them to cold exposure and conducted gene expression analysis in iWAT. Although PRDM16 was dispensable for constitutive peroxisomal biogenesis, its knockout completely blocked the cold-induced increase in peroxisomal biogenesis in iWAT, without affecting the expression of genes involved in lysosomal function, such as Ctsb and Lipa (Figure 1E).

To understand the role of peroxisomes in adipose tissue thermogenesis, we performed gene expression analysis on BAT, inguinal WAT (iWAT), and gWAT from mice kept at room temperature (22°C) or subjected to cold exposure (4°C) (Figure 1). Cold exposure increased the expression of genes involved in peroxisomal biogenesis in BAT, as well as in iWAT, which is highly susceptible to cold-induced browning (15), but not in gWAT (Figure 1A). These data suggest that peroxisomes in brown and beige adipocytes are involved in thermogenesis.

PRDM16 regulates cold-induced peroxisomal biogenesis. Adipose tissue–mediated thermogenesis requires PRDM16, a large zinc finger–containing transcription factor that regulates gene expression by interacting with and modulating the activity of other transcription factors, including C/EBPβ, PGC-1α, PPARα, and PPARγ (15). Microarray analysis identified Pex16 as a potential transcriptional target of PRDM16 (16). Thus, we sought to determine whether PRDM16 might be involved in peroxisomal biogenesis. To examine whether PRDM16 regulates Pex16 expression, we created a GFP reporter construct under the control of a ~2 kb mouse Pex16 promoter. Overexpression of PRDM16 in COS-7 cells increased GFP expression (Figure 1B). To quantify the effect of PRDM16 on the Pex16 promoter, we also generated a luciferase reporter plasmid. Overexpression of PRDM16 increased the expression of luciferase under the control of the Pex16 promoter (Figure 1C). To determine whether PRDM16 directly regulates Pex16 gene expression, we isolated the stromal vascular fraction (SVF) of BAT from WT C57BL/6 (C57) mice, infected the cells with retrovirus expressing FLAG-PRDM16, and performed ChIP assays using an anti-FLAG antibody, followed by qPCR using primers targeting various regions of the Pex16 promoter. PRDM16 interacted with a proximal region of the Pex16 promoter (Figure 1D). Together, these data strongly suggest that PRDM16 directly regulates the Pex16 expression.

To determine whether PRDM16 is required for the expression of other peroxisomal genes and is involved in cold-induced peroxisomal biogenesis, we generated mice with adipose-specific PRDM16 knockout (PRDM16-AKO) by crossing PRDM16lox/lox animals (17) with adiponectin-Cre mice (18). We maintained 6-week-old PRDM16-AKO and control mice at room temperature or subjected them to cold exposure and conducted gene expression analysis in iWAT. Although PRDM16 was dispensable for constitutive peroxisomal biogenesis, its knockout completely blocked the cold-induced increase in peroxisomal biogenesis in iWAT, without affecting the expression of genes involved in lysosomal function, such as Ctsb and Lipa (Figure 1E). In the classical BAT of cold-treated mice, PRDM16 inactivation resulted in only a modest (20%–30%) reduction in the expression of certain peroxisomal biogenesis genes, and even Ucp1, a known PRDM16 target gene, was decreased only 40% (Supplemental Figure 1D), consistent with previous studies suggesting that a related transcription factor, PPRD1, can compensate for the loss of PRDM16 in BAT, particularly in younger mice (19).
in the absence of peroxisomes (Figure 2F). Together, these data demonstrate that Pex16 is critical for peroxisomal biogenesis in adipose tissue.

Mice with adipose-specific knockout of Pex16 have increased diet-induced obesity and impaired thermogenesis. To determine the effect on adiposity and metabolism, we phenotypically characterized the mice (Figure 3). In the mice fed a normal chow diet, no significant difference in body weight between the genotypes was observed (Figure 3A). High-fat feeding resulted in late-onset obesity in Pex16-AKO mice (Figure 3B), a phenotype resembling that in animals with adipose-specific knockout of PRDM16 (17). Interestingly, this effect of high-fat feeding was only seen in the mice housed at room temperature (22°C), which is a mild cold challenge for mice that achieve thermoneutrality at approximately 30°C (21). At thermoneutrality, control and Pex16-AKO mice weighed the same (Figure 3C), suggesting that the increased diet-induced obesity in the room temperature–housed knockout mice likely reflects impaired thermogenesis.

At room temperature, body composition analysis performed after 20 weeks on HFD, when the weight curves had begun to diverge, indicated that the knockout mice had significantly increased adiposity (Figure 3D). The gWAT depot weighed significantly more in the knockout mice (Figure 3E), while chow-fed animals showed no phenotypic differences (Supplemental Figure 3, A and B). Histologic analysis indicated that white adipocytes were larger in HFD-fed knockout animals (Figure 3F and Supplemental Figure 3, C and D). The increased adiposity was observed despite the fact that there was no difference in food intake (Supplemental Figure 3E) or physical activity (Supplemental Figure 3F). Assessment of glucose homeostasis indicated that although glucose tolerance was significantly impaired in chow-fed Pex16-AKO mice (Supplemental Figure 3G), the difference between the genotypes was lost in animals fed HFD for 14 weeks (Supplemental Figure 3H).

We next determined the effect of Pex16 inactivation on energy expenditure and thermogenesis. Indirect calorimetry performed in mice fed HFD for 15 weeks at 22°C indicated that there was no difference in resting energy metabolism (Supplemental Figure 3, I–K), consistent with previous studies suggesting that indirect calorimetry is not sufficiently sensitive to detect subtle changes in energy expenditure that result in modest obesity over an extended period (17, 22). However, the oxygen consumption rate (OCR; VO₂) after treatment of mice with the β-adrenergic receptor agonist norepinephrine (NE) was significantly decreased in
Pex16-AKO mice (Figure 3G), suggesting that BAT function might be impaired. Consistent with this possibility, histologic analysis of BAT indicated there was a marked accumulation of lipids in BAT after cold treatment in the Pex16-AKO mice (Figure 3H). BAT from cold-treated knockout animals was pale in appearance (Figure 3I) and had significantly higher triglyceride content (Figure 3J).

To determine whether the increased adiposity and elevated accumulation of lipids in BAT were due to impaired thermogenesis, we subjected singly housed mice to acute cold exposure (4°C). Pex16-AKO mice were severely cold intolerant (Figure 3K) and died from the cold challenge within 8–40 hours (Figure 3L). Together, these data suggest that peroxisomes are critical for brown fat–mediated thermogenesis.

Inhibition of peroxisomal biogenesis blocks cold-induced mitochondrial fission and impairs mitochondrial function in brown and beige adipocytes. Since mitochondria are critical for thermogenesis and mitochondrial respiration accounts for most of the cellular oxygen consumption, the impaired thermogenesis and reduced rate of NE-induced oxygen consumption in Pex16-AKO mice prompted us to examine the effects of Pex16 inactivation on mitochondrial structure and function in BAT (Figure 4). Transmission electron microscopic (TEM) analysis indicated that mitochondria in the BAT of control mice at room temperature had an elliptical shape (Figure 4A). Cold exposure resulted in the appearance of circular mitochondria in these mice with an aspect ratio of close to 1 (Figure 4B), and the total number of mitochondria per cell significantly increased (Figure 4C), consistent with previous studies suggesting that β-adrenergic stimulation promotes mitochondrial fission in brown adipocytes (23). Interestingly, this cold-induced mitochondrial division was blocked in the knockout BAT, and the mitochondria maintained an elongated morphology. Nevertheless, the mitochondria in the Pex16-AKO brown adipocytes appeared to have healthy cristae (Figure 4A), and the membrane potential measured using tetramethylrhodamine, ethyl ester (TMRE) dye was also unaffected following Pex16 knockdown in brown adipocytes (Supplemental Figure 4A). TEM analysis also indicated that lipid droplets were larger in BAT of Pex16-AKO mice as compared with control mice (Figure 4A and Supplemental Figure 4B).

Consistent with the possibility that loss of peroxisomes impairs mitochondrial division in BAT, Pex16 knockout significantly decreased mitochondrial DNA (mtDNA) copy number in mice at room temperature and completely blocked the cold-induced increase in mtDNA content (Figure 4D). Pex16 knockout also suppressed the cold-induced increase in mtDNA content in iWAT (Figure 4E), suggesting that similar mechanisms might be at play in both BAT and iWAT. qPCR analysis in BAT from cold-treated mice indicated that the mitochondrial transcripts cytochrome c oxidase I (MtCo1), MtCo2, and mitochondrially encoded NADH:ubiquinone oxidoreductase core subunit 6 (MtNd6) — representing components of the oxidative phosphorylation (OXPHOS) pathway — were significantly decreased, while nuclear-encoded genes for mitochondrial proteins (e.g., Ucp1 and Cs) or factors involved in mitochondrial biogenesis (Tfam and Nrf1) were unaffected (Figure 4F). Western blot analysis confirmed that the expression levels of UCP1 and cytochrome c oxidase IV (COX IV), a nuclear-encoded component of the mitochondrial electron transport chain, were unaffected with Pex16 inactivation in BAT (Supplemental Figure 4C).
Mitochondrial division requires dynamin-related protein 1 (Drp1), a cytosolic GTPase that is recruited to the mitochondrial outer membrane during fission (24). Gene expression of Drp1, other factors involved in mitochondrial fission (Fis1 and Mff), and factors involved in mitochondrial fusion (Mfn1, Mfn2, and Opa1) were unchanged in BAT with Pex16 inactivation (Figure 4F). Moreover, Western blot analysis indicated that levels of Drp1 were unchanged in the mitochondrial fractions isolated from BAT of cold-treated control and Pex16-AKO mice (Supplemental Figure 4D). This suggests that inhibition of peroxisomal biogenesis in brown adipocytes does not block Drp1 recruitment to mitochondria or its gene expression, but might inhibit its ability to fragment mitochondria.

Cell-autonomous effects of Pex16 inactivation on mitochondrial morphology and function. To determine whether the effects of Pex16 inactivation on mtDNA content and morphology were cell autonomous, we treated BAT SVF cells with lentiviral shRNA for Pex16 (Figure 5). Unlike knockdown of Pex16 in undifferentiated 3T3-L1 cells, which has been shown to block PPARγ signaling and adipogenesis (25), knockdown of Pex16 during the late stage of differentiation in BAT SVF cells (Figure 5A) did not decrease adipogenic gene expression or accumulation of lipid droplets (Supplemental Figure 5, A and B). However, this intervention significantly decreased mtDNA (Figure 5B). It is noteworthy that although mitochondria in BAT were fragmented only after cold exposure of mice (Figure 4A), mitochondria in cultured brown adipocytes were constitutively fragmented (Figure 5C), perhaps because cell culture represents a nutrient surplus condition. Under such conditions, mitochondria tend to be more fragmented and exhibit reduced bioenergetic efficiency (26). Pex16 knockdown resulted in elongated mitochondria that formed net-like structures, a characteristic feature of impaired mitochondrial fission, as observed with genetic inactivation of Drp1 (27–29). Treatment of BAT SVF cells with Mdivi-1, a cell-permeable inhibitor of Drp1 (30), also resulted in tubular mitochondria, and Pex16 knockdown did not further exacerbate this phenotype (Figure 5C). The mitochondrial morphology was quantified by visual inspection of cells to determine the percent-age of cells exhibiting fragmented, fused, or intermediate (partially fragmented) mitochondria (Figure 5D).

We next determined whether mitochondrial function was altered due to peroxisome deficiency in brown adipocytes. Basal and NE-stimulated OCR measured using a Seahorse XF24 Extracellular Flux Analyzer was significantly decreased with Pex16 knockdown (Figure 5E), consistent with the decreased expression of OXPHOS genes (Figure 4F). We also performed high-resolution respirometry using an OROBOROS Instruments Oxygraph-02k system to assess mitochondrial function in BAT and iWAT from cold-treated control and Pex16-AKO mice after sequential addition of different substrates, including octanoyl carnitine; pyruvate; glutamate and malate; and ADP and succinate. There was a trend for the mitochondrial respiration to be decreased in BAT of Pex16-AKO mice in response to various substrates, but the effects did not reach statistical significance. However, the maximum respiration after the addition of the mitochondrial uncoupler FCCP was significantly lower in BAT of Pex16-AKO mice (Figure 5F). Mitochondrial respiration was significantly lower in iWAT of Pex16-AKO mice after addition of various substrates and FCCP (Figure 5G). Together, these data suggest that inhibition of peroxisomal biogenesis impairs cold-induced mitochondrial division, resulting in decreased mtDNA content and disruption of mitochondrial function in brown and beige fat.

BAT-specific Pex16 knockout reduces respiration but is not sufficient to fully impair thermogenesis. To understand the relative contribution of BAT versus WAT in peroxisome-dependent regulation of thermogenesis, we generated mice with BAT-specific knockout of Pex16 (Pex16-BKO) by crossing Pex16lox/lox mice with Ucp1-Cre transgenic mice (Figure 6). Cre-mediated recombination at the Pex16 locus in BAT was confirmed by PCR (Figure 6A), and Western blot analysis demonstrated that Pex16 was selectively knocked out in BAT and not in WAT depots (Figure 6B). Gene expression analysis indicated that levels of the mitochondrial transcripts MtCo1, MtCo2, and MtNd6 were significantly decreased in BAT of Pex16-BKO mice (Figure 6C). C3 was also decreased modestly, but significantly. Indirect calorimetry demonstrated that VO2 was significantly lower after treatment with NE in the mutant mice (Figure 6D). Nevertheless, the Pex16-BKO mice were surprisingly only modestly less cold tolerant than control mice (Figure 6E). This was not because of a compensatory increase in the gene expression of Ucp1 or genes involved in UCP1-independent mechanisms of thermogenesis, including SERCA2b-dependent Ca2+ cycling and creatine metabolism pathways (31, 32), in iWAT (Figure 6F).

Together, these results suggest that peroxisomal biogenesis in both BAT and WAT is required for thermogenesis. Although knockout of Pex16 in BAT alone reduces respiration, it is not sufficient to fully impair thermogenesis.

Pex16 knockout impairs peroxisomal and mitochondrial fatty acid oxidation. Since inhibition of mitochondrial fatty acid oxidation (FAO) has been shown to result in increased accumulation of lipid droplets in BAT and impaired thermogenesis (33), phenotypes resembling those of our Pex16-AKO mice, we sought to determine whether mitochondrial and/or peroxisomal FAO pathways were affected by Pex16 deficiency (Figure 7). Although Pex16 knockout appears to result in degradation of the peroxisomal FAO enzyme acyl-CoA oxidase 1 (Acox1) protein (Figure 2F), its gene
expression was not decreased, but rather slightly increased (Figure 7A). Other FAO genes, including those for the peroxisomal enzyme 3-ketoacyl-CoA thiolase (Acaa1) and the mitochondrial enzyme carnitine palmitoyltransferase 1 (Cpt1), which are thought to be PPARα transcriptional targets, as well as Ppara itself, were significantly increased in BAT of Pex16-AKO mice (Figure 7A). The gene expression of some FAO enzymes, including peroxisomal multifunctional protein 2 (Hsd17b4) and medium-chain acyl-CoA dehydrogenase (Acadm), was not significantly affected. The increased expression of certain PPARα target genes is consistent with previous studies suggesting that peroxisomal FAO regulates metabolism of an endogenous ligand of this nuclear receptor (34).

Direct measurement of FAO using radiolabeled substrates indicated that oxidation of lignoceric acid (C24:0), a VLCFA that is oxidized exclusively in peroxisomes, as well as oxidation of palmitate (C16:0), which occurs primarily in mitochondria, was significantly blocked with Pex16 knockout (Figure 7B and C). To determine whether the impaired mitochondrial FAO simply reflected a general decrease in mitochondrial function in Pex16-AKO mice, we normalized the palmitate oxidation to citrate synthase activity.

**Figure 4. Pex16 inactivation impairs mitochondrial division and function in brown and beige adipocytes.** (A) TEM analysis of BAT from control and Pex16-AKO mice kept at room temperature or subjected to cold exposure. Peroxisomes (black dots) were detected by staining using DAB. Note the difference in mitochondrial morphology between the genotypes at 4°C. Scale bars: 500 nm. P, peroxisome; M, mitochondria; LD, lipid droplet. (B) Aspect ratio (ratio of major axis length to minor axis length) measured in BAT mitochondria. The data are based on 15 mitochondria per condition. (C) Number of mitochondria per cell based on TEM images of BAT taken at ×1000–×2000 magnification. Data are the average of 8 cells per condition. (D and E) mtDNA copy number normalized to nuclear DNA measured by qPCR in BAT and iWAT; for BAT, n = 6 per genotype at 22°C and 3 per genotype at 4°C; for iWAT, n = 4 per genotype under each condition. (F) Gene expression analysis in BAT of cold-treated mice; n = 4–5. Data are expressed as mean ± SEM and were analyzed by 1-way ANOVA followed by Fisher’s least significant difference (LSD) test (B–E) or by Student’s t test (F); *P < 0.05; **P < 0.01; ***P < 0.001.
decreased, while the expression of genes involved in peroxisomal biogenesis and mitochondrial FAO, and of other genes in the peroxisomal FAO pathway, was unchanged (Figure 7E). Acox1 knockout also had no effect on the expression of Acox2 and Acox3, which are involved in branched-chain FAO and/or bile acid metabolism (37) and are present at much lower levels as compared with Acox1 in BAT and iWAT (Supplemental Figure 7, A and B).

Knockout of Acox1 in BAT and iWAT was confirmed by Western blot analysis (Figure 7F). Inhibition of VLCFA oxidation due to Acox1 inactivation was confirmed by measuring catabolism of stable isotope–labeled docosanoic acid (D3-C22:0) to D3-C16:0 via mass spectrometric analysis in control and Acox1-KO iWAT SVF cells (Figure 7G). Surprisingly, adipose-specific inactivation of Acox1 did not affect diet-induced obesity (Figure 7H), nor did it impair cold tolerance (Figure 7I) or reduce BAT mitochondrial copy number (Figure 7J). Knockdown of Acox2 or Acox3 in BAT SVF cells using lentiviral shRNA (Supplemental Figure 7C) also did not affect mtDNA content (Supplemental Figure 7D). Together, these data suggest that the increased adiposity, impaired thermogenesis, and decreased, while the expression of genes involved in peroxisomal biogenesis and mitochondrial FAO, and of other genes in the peroxisomal FAO pathway, was unchanged (Figure 7E). Acox1 knockout also had no effect on the expression of Acox2 and Acox3, which are involved in branched-chain FAO and/or bile acid metabolism (37) and are present at much lower levels as compared with Acox1 in BAT and iWAT (Supplemental Figure 7, A and B).

Knockout of Acox1 in BAT and iWAT was confirmed by Western blot analysis (Figure 7F). Inhibition of VLCFA oxidation due to Acox1 inactivation was confirmed by measuring catabolism of stable isotope–labeled docosanoic acid (D3-C22:0) to D3-C16:0 via mass spectrometric analysis in control and Acox1-KO iWAT SVF cells (Figure 7G). Surprisingly, adipose-specific inactivation of Acox1 did not affect diet-induced obesity (Figure 7H), nor did it impair cold tolerance (Figure 7I) or reduce BAT mitochondrial copy number (Figure 7J). Knockdown of Acox2 or Acox3 in BAT SVF cells using lentiviral shRNA (Supplemental Figure 7C) also did not affect mtDNA content (Supplemental Figure 7D). Together, these data suggest that the increased adiposity, impaired thermogenesis, and decreased, while the expression of genes involved in peroxisomal biogenesis and mitochondrial FAO, and of other genes in the peroxisomal FAO pathway, was unchanged (Figure 7E). Acox1 knockout also had no effect on the expression of Acox2 and Acox3, which are involved in branched-chain FAO and/or bile acid metabolism (37) and are present at much lower levels as compared with Acox1 in BAT and iWAT (Supplemental Figure 7, A and B).

Knockout of Acox1 in BAT and iWAT was confirmed by Western blot analysis (Figure 7F). Inhibition of VLCFA oxidation due to Acox1 inactivation was confirmed by measuring catabolism of stable isotope–labeled docosanoic acid (D3-C22:0) to D3-C16:0 via mass spectrometric analysis in control and Acox1-KO iWAT SVF cells (Figure 7G). Surprisingly, adipose-specific inactivation of Acox1 did not affect diet-induced obesity (Figure 7H), nor did it impair cold tolerance (Figure 7I) or reduce BAT mitochondrial copy number (Figure 7J). Knockdown of Acox2 or Acox3 in BAT SVF cells using lentiviral shRNA (Supplemental Figure 7C) also did not affect mtDNA content (Supplemental Figure 7D). Together, these data suggest that the increased adiposity, impaired thermogenesis, and
mitochondria dysfunction caused by Pex16 knockout-mediated inhibition of peroxisomal biogenesis in adipose tissue are not likely due to a loss of ability to oxidize fatty acids in peroxisomes.

**Knockdown of Pex16 in brown adipocytes does not increase mitochondrial ROS production.** We next explored the possibility that mitochondrial dysfunction associated with impaired peroxisomal biogenesis could be related to an altered mitochondrial redox state. Intracellular redox state is thought to influence mitochondrial dynamics (38). Moreover, oxidative stress has been reported to cause degradation of mtDNA (39). To determine whether loss of peroxisomes affects mitochondrial redox state, we used a lentivirus-encoded redox-sensitive GFP possessing a mitochondrial localization sequence (Mito-roGFP) to assess changes in mitochondrial ROS levels in BAT SVF cells treated with scrambled or Pex16 shRNA. This ratiometric sensor has certain surface-exposed residues mutated to cysteine, permitting dithiol formation, and it exhibits two excitation maxima, one at 400 nm (reflective of oxidative state) and another at the normal 484 nm (reflective of reductive state) (40). The ratio of fluorescence measured following differential excitation represents the mitochondrial redox state. Interestingly, knockdown of Pex16 decreased GFP fluorescence following excitation at either 400 or 484 nm (Supplemental Figure 8A), presumably reflecting the decreased mitochondrial mass due to the loss of peroxisomes, and the ratio of two fluorescence readouts was unchanged in Pex16-knockdown cells as compared with control cells (Supplemental Figure 8B). These data suggest that mitochondrial dysfunction due to impaired peroxisomal biogenesis is likely not due to increased mitochondrial oxidative stress.

**Presence of peroxisome-derived phospholipids in mitochondria.** Another potential mechanism for the mitochondrial dysfunction and impaired thermogenesis in the peroxisome-deficient mice could be altered mitochondrial membrane phospholipid composition, leading to disruption of mitochondrial dynamics. To investigate this possibility, we determined whether peroxisome-derived lipids are present in mitochondria and if inhibition of their synthe-
Figure 7. Pex16-AKO mice have impaired FAO, but adipose-specific inhibition of peroxisomal FAO is not sufficient to promote diet-induced obesity or impair thermogenesis. The floxed mice were crossed with an adiponectin-Cre mouse to generate Acox1-AKO mice. gRNA, guide RNA; ssODN, single-stranded oligodeoxyribonucleotide. (E) qPCR analysis of FAO and peroxisomal biogenesis genes; n = 3. (F) Western blot analysis of Acox1 knockout in BAT and iWAT. (G) Control and Acox1-KO iWAT SVF cells were incubated with D3-C22:0, whose catabolism to D3-C16:0 was measured mass spectrometrically. FAO was expressed as ratio of D3-C16:0 to D3-C22:0; n = 4. (H) Body weight of control and Acox1-AKO mice fed an HFD and maintained at normal room temperature; n = 13-18. (I) Cold tolerance was determined by measuring rectal temperature at the indicated times after cold exposure; n = 4-5. (J) mtDNA content normalized to nuclear DNA in BAT of control and Acox1-AKO mice subjected to cold exposure; n = 3. Data are expressed as mean ± SEM. Student’s t test was used for analysis of the data in A-C, E, G, and J were analyzed by Student’s t test. Two-way ANOVA with Bonferroni’s post hoc test was used for analysis of the data in I. *P < 0.05; **P < 0.01; ***P < 0.001.
sis phenocopies the effects of disrupting peroxisomal biogenesis on mitochondrial morphology and function (Figure 8). Peroxisomes are critical for synthesis of ether lipids, a special class of phospholipids in which the hydrocarbon chain at the sn-1 position of the glycerol backbone is attached by an ether bond, as opposed to an ester bond in the more common diacyl phospholipids (41, 42). Plasmalogens, the most common form of ether lipids, have a cis double bond adjacent to the ether bond. The initial steps of ether lipid synthesis take place in peroxisomes (Figure 8A). Notably, Pex16 knockout resulted in degradation of the plasmalogen synthetic enzymes alkylglyceronephosphosphate synthase (AGPS) and glyceronephosphate O-acyltransferase (GNPAT) in BAT and iWAT (Figure 8, B and C). Targeted lipidomics analysis of mitochondria isolated from BAT of WT mice indicated that plasmalogens are present at levels close to those of cardiolipins (CLs) (Figure 8D), which are an important component of mitochondrial membranes (43). Since isolated mitochondria are known to be contaminated with other organelles, especially peroxisomes (44), we performed immunoblot analysis of mitochondrial and peroxisomal markers to assess the purity. Our results suggest that the mitochondrial fraction was enriched in the known mitochondrial proteins COX IV and Tomm20, but had only small amounts of the peroxisomal proteins PMP70 and catalase (Supplemental Figure 9B). Moreover, our lipidomics analysis suggests that CLs account for approximately 10% of the total phospholipids in BAT mitochondria, which is within the range of previously reported levels of 10%–15% in the mitochondria of various cell types (43), suggesting that our isolated mitochondria are relatively pure.

Knockout of Pex16 reduced the levels of ethanolamine plasmalogens without affecting the total abundance of diacyl phosphatidylethanolamine (Figure 8, E and F) or CL (Supplemental Figure 9B). Ether-linked phosphatidylecholines (PCs), including choline plasmalogens, were present at very low abundance in mitochondria, and certain species of diacyl-PC were increased with Pex16 knockout (Supplemental Figure 9C).

Inhibition of plasmalogen synthesis affects mitochondrial dynamics and function in adipocytes. We next determined whether inhibition of plasmalogen synthesis affects mitochondrial morphology and function in cultured adipocytes. We previously identified the enzyme that catalyzes the terminal peroxisomal step in ether lipid synthesis and named the protein PexRAP (45). Since PexRAP also appears to have other functions related to regulation of gene expression and its inactivation results in only partial reduction in plasmalogens (46), we knocked down expression of GNPAT, the enzyme responsible for the first step in plasmalogen production, to determine the effects on mitochondria. As observed with Pex16 knockout, GNPAT knockdown during the late stage of differentiation in BAT SVF cells did not affect adipogenic gene expression or lipid droplet formation (Supplemental Figure 5, C and D). Interestingly, GNPAT knockdown markedly altered mitochondrial morphology and decreased mtDNA (Figure 8, G and H), mimicking the effect of Pex16 knockdown (Figure 5). Moreover, basal and NE-stimulated OCRs were significantly decreased with GNPAT knockdown (Figure 8D), similarly to Pex16 knockdown (Figure 5E).

Dietary supplementation of plasmalogen precursors rescues thermogenesis in Pex16-AKO mice. Finally, we explored the possibility that restoration of plasmalogen levels could relieve mitochondrial defects and impaired thermogenesis in Pex16-AKO mice (Figure 9). To this end, we treated control and Pex16-AKO mice with a chow diet containing alkylglycerols (16:0-AG and 18:0-AG), ether lipid precursors that enter the synthetic pathway downstream of the peroxisomal steps and are known to be incorporated into plasmalogens (41). Treatment of mice with this diet increased the levels of several species of ethanolamine plasmalogens in mitochondria from BAT in Pex16-AKO mice (Figure 9A) and restored the total plasmalogen content in mitochondria to control levels (Supplemental Figure 10A). TEM analysis in BAT from cold-treated mice indicated that AG treatment increased the circularity and abundance of mitochondria in Pex16-AKO mice (Figure 9, B–D), suggesting that restoration of plasmalogens rescues cold-induced division of mitochondria. Consistent with this notion, the AG diet increased BAT mtDNA copy number in Pex16-AKO mice (Figure 9E), without affecting the expression of genes involved in mitochondrial biogenesis or dynamics (Supplemental Figure 10B). Indirect calorimetry showed that AG increased NE-stimulated oxygen consumption in control and Pex16-AKO mice (Figure 9F). Interestingly, this effect on oxygen consumption was not seen in animals housed at thermoneutrality (Supplemental Figure 10C), suggesting that plasmalogens promote energy expenditure by activating thermogenesis. In support of this possibility, the AG treatment rescued cold intolerance in Pex16-AKO mice (Figure 9G). The protective effects of AG required several weeks of treatment, whereas a short-term (1-week) treatment did not mitigate cold intolerance in Pex16-AKO mice (Supplemental Figure 10D). Although dietary AG is absorbed intact, the vinyl ether bond can be oxidized in intestinal mucosal cells (41). Thus, whereas plasma lipids change rapidly within a few days of dietary manipulation, changes in erythrocytes and other tissues require several weeks of treatment (41, 47).

To understand the systemic effects of AG, we determined its role in fatty acid and pyruvate oxidation in BAT, skeletal muscle, and liver in Pex16-AKO and control mice. There were no genotype-specific effects on palmitate or pyruvate oxidation in muscle and liver (Supplemental Figure 11, A–D). However, the AG treatment significantly decreased palmitate oxidation and resulted in a trend toward increased pyruvate oxidation in liver (Supplemental Figure 11, C and D). In BAT, Pex16 knockout impaired palmitate oxidation, but AG treatment did not reverse this effect (Figure 9H). Interestingly, Pex16 inactivation also resulted in a trend toward impaired pyruvate oxidation, which was restored by AG in BAT (Figure 9I). The defect in glucose metabolism in Pex16-AKO mice is likely at the level of mitochondria in adipose tissue, since knockout of Pex16 in cultured brown adipocytes did not block insulin-stimulated translocation of the Glut4 glucose transporter (Supplemental Figure 11E).

Together, these results support our notion that AG rescues thermogenesis in Pex16-AKO mice by relieving the defect in cold-induced mitochondrial division in adipose tissue. However, we cannot rule out the possibility that metabolism of AG by other tissues could potentially also contribute to its beneficial effects, since it increased VO₂ in both control and Pex16-AKO mice.

Discussion
Our studies suggest that peroxisomal biogenesis increases in adipose tissue in response to cold exposure, in a manner dependent
Figure 8. Peroxisome-derived lipids are present in mitochondria, and inhibition of their synthesis reduces mtDNA content and impairs mitochondrial function. (A) Ether lipid synthetic pathway. The initial steps for synthesis of ether lipids, including plasmalogens, take place in peroxisomes, generating 1-O-alkyl-glycerol-3-phosphate (AGP), a precursor for ether-linked analogs of PC and phosphatidylethanolamine. DHAP, dihydroxyacetone phosphate. (B and C) Western blot analysis suggesting that ether lipid synthetic enzymes are degraded in BAT (B) and iWAT (C) of Pex16-AKO mice (D) Targeted lipidomics analysis of mitochondrial phospholipids in BAT of WT C57 mice. PS, phosphatidylserine; PG, phosphatidylglycerol; aPC, alkyl ether PC; pPC, plasmalogen PC; PE, phosphatidylethanolamine; pPE, plasmalogen PE; n = 5. (E) Levels of various plasmalogen PE species in the mitochondrial fraction of BAT; n = 9–10. (F) Total diacyl and plasmalogen PE content in BAT mitochondria. (G) BAT SVF cells stably expressing Mito-roGFP were differentiated into adipocytes and then treated with scrambled or GNPAT shRNA and analyzed 5 days later for mitochondrial morphology using confocal microscopy. Images are representative of 3 separate experiments. Original magnification, x60. (H) Differentiated BAT SVF cells were treated with scrambled or GNPAT shRNA. Five days later, mtDNA copy number normalized to nuclear DNA was measured by qPCR; n = 5. (I) Effect of shRNA-mediated knockdown of GNPAT on OCR was measured in BAT SVF cells using a Seahorse XF24 Extracellular Flux Analyzer; n = 8. Data are expressed as mean ± SEM and were analyzed by Student’s t test. *P < 0.05.
on the thermogenic transcription factor PRDM16, suggesting that the transcriptional regulation of thermogenesis and de novo peroxisome formation is coordinated. Using mice with adipose-specific knockout of Pex16, we show that disruption of peroxisomal biogenesis impairs cold-induced adipose tissue thermogenesis without affecting thermogenic gene expression. The loss of peroxisomes also impaired diet-induced thermogenesis, resulting in late-onset obesity, similar to adipose-specific knockout of Prdm16 in mice (17), suggesting that PRDM16-mediated regulation of adiposity might be related to its control of peroxisomal biogenesis. Together, our results indicate that peroxisomes are critical for adipose tissue thermogenesis, and mice with adipose-specific peroxisome deficiency have increased adiposity due to their inability to mount a diet-induced, NE-recruited thermogenic response.

Recent studies suggest that mitochondria are involved in de novo peroxisome formation (3). By pursuing the molecular mechanism through which peroxisomes regulate adipose tissue thermogenesis, our work suggests that peroxisomes are reciprocally involved in mitochondrial division. As highly dynamic organelles, mitochondria alter their abundance and morphology through fission and fusion processes, depending on metabolic context (26). Fragmented mitochondria are observed during nutrient excess (48). In contrast, elongated mitochondria are associated with conditions that require increased metabolic efficiency, such as starvation (49, 50). Mitochondrial elongation is also linked to decreased uncoupled respiration (28). Accordingly, previous studies show that β-adrenergic receptor activation-induced mitochondrial fission serves as a critical physiological regulator of energy expenditure and thermogenic function of brown adipocytes (23). Although the precise molecular mechanism is unclear, fragmented mitochondria are thought to exhibit increased uncoupled respiration by directing FAO toward heat production and energy expenditure, instead of ATP synthesis. Our studies suggest that the loss of peroxisomes blocks cold-induced mitochondrial fission in adipose tissue, resulting in elongated mitochondria and impaired thermogenesis.

Unlike pan-adipose Pex16 inactivation, BAT-specific knock-out of the peroxisomal biogenesis factor was not sufficient to fully impair thermogenesis, suggesting that beige fat plays a physiologically significant role in peroxisome-dependent regulation of thermogenesis. Like brown adipocytes, beige adipocytes are enriched in mitochondria. Increasing evidence supports the importance of beige adipocyte mitochondria in UCP1-dependent and -independent mechanisms of thermogenesis and regulation of adiposity and metabolism (32, 51, 52). Our results indicate that peroxisomes in both brown and beige fat may be involved in regulating mitochondrial dynamics and function to impact thermogenesis. However, lack of a Cre line that specifically targets WAT makes it difficult to experimentally distinguish the thermogenic contribution of beige fat from that of BAT and to assess other possible functions of Pex16 in WAT that could potentially impact adiposity and metabolism through mechanisms besides thermogenic regulation.

One potential explanation for the formation of elongated mitochondria due to Pex16 inactivation could be that peroxisome deficiency promotes mitochondrial fusion instead of impairing fission. However, the decreased mtDNA copy number argues against increased fusion being a primary effect. Regulation of mtDNA copy number is considered a primary role of mitochondrial dynamics (53). Consistent with the notion that peroxisome deficiency results in impaired mitochondrial fission, our results suggest that Pex16 inactivation in adipocytes causes mitochondria to elongate and form tubular network structures, as well as causing mtDNA loss and impaired mitochondrial function, phenocopying the previously reported effects of directly inhibiting mitochondrial fission through Drp1 inactivation (27–29).

Mitochondrial dysfunction in the context of peroxisome deficiency has been well documented for hepatocytes (54). Although the underlying molecular mechanism remains unknown, lack of peroxisomes in hepatocytes results in severe mitochondrial abnormalities, including destruction of the inner mitochondrial membrane, distortion of cristae structure, decreased membrane potential, and increased ROS production. Notably, these abnormalities appear to be selective for hepatocytes (55) and are all distinct from the mitochondrial changes resulting from the inhibition of peroxisomal biogenesis in adipocytes reported here. Unlike hepatocytes, which normally have numerous large nucleoid (crystallloid core)–containing peroxisomes (~0.7-μm diameter), other cell types, including adipocytes, have fewer and smaller peroxisomes lacking nucleoid, referred to as microperoxisomes (~0.1-μm diameter) in older literature (56). In contrast to the effects of peroxisome deficiency in hepatocytes, our results suggest the mitochondria in the peroxisome-deficient adipocytes are visibly normal, with intact cristae and unaffected membrane potential and without increased ROS production. Instead, our data strongly suggest that the primary defect in adipocytes is impaired mitochondrial division, resulting in mtDNA loss, decreased expression of mitochondrially encoded components of the electron transport chain, and reduced rate of coupled and uncoupled respiration.

These phenotypes do not appear to be related to loss of the ability to oxidize VLCFAs or to an altered redox state in adipocytes in the absence of peroxisomes. Instead, peroxisomal plasmalogen synthesis appears to be involved in the mechanism. Due to the presence of a vinyl ether bond at the sn-1 position of their glycerol backbone, plasmalogens tend to form non-lamellar lipid structures, such as inverted hexagonal configurations, suggesting that they might be involved in membrane dynamics (57, 58). Our results indicate that plasmalogens are present in adipocyte mitochondria and disruption of their synthesis impairs mitochondrial fission, perhaps by altering biophysical properties of the outer mitochondrial membrane and blocking Drp1-mediated membrane constriction.

Collectively, our data suggest that peroxisomes regulate adipose tissue thermogenesis by directing plasmalogens to mitochondria to mediate mitochondrial fission. Manipulating plasmalogen production through dietary or pharmacological means could improve the thermogenic function of brown and beige fat, perhaps leading to a novel treatment option for obesity.

Methods

Further information can be found in Supplemental Methods, available online with this article.

Mouse models. PRDM16Lox/Lox mice were obtained from the Jackson Laboratory (stock 024992) and have been previously described (17). Mice with the potential for conditional Pex16 knockout were
Figure 9. Dietary supplementation of plasmalogens rescues mitochondrial morphology and function and improves cold tolerance in Pex16-AKO mice.

(A) Mass spectrometric analysis of PE plasmalogens in the mitochondrial fractions from control and Pex16-AKO mice treated with or without AG for 8 weeks; n = 5. (B) TEM analysis of mitochondrial morphology in BAT of control and Pex16-AKO treated with or without AG, followed by cold exposure. Scale bar: 500 nm. (C) Aspect ratio measured in BAT mitochondria from control and Pex16-AKO mice. The data are based on 26 mitochondria per condition. (D) Number of mitochondria per cell based on TEM images of BAT taken at ×1000–×2000 magnification. The data are average of 6–8 cells per condition. (E) mtDNA measured by PCR in BAT of control and Pex16-AKO mice treated with or without AG, followed by cold exposure; n = 6–7. (F) VO2 was measured using indirect calorimetry before and after intraperitoneal NE injection; n = 8–9. (G) Cold tolerance was determined by measuring rectal temperature prior to and after 6 hours of cold exposure; n = 6–8. (H and I) Fatty acid and pyruvate oxidation assays in BAT; n = 3–4. Data are expressed as mean ± SEM and were analyzed by 1-way ANOVA, followed by Fisher’s LSD test (A, C–E, and G–I), or 2-way ANOVA with Bonferroni’s post hoc test (F); *P < 0.05; **P < 0.01; ***P < 0.001.
obtained from the EUCOMM repository. To generate mice with conditional alleles of Pex16, the lacZ/neo selection cassette was removed by crossing the mice with transgenic mice expressing Flp recombinase under the control of the actin promoter (The Jackson Laboratory). The Flp transgene was selected against in subsequent crosses. Acox2loxP/loxP mice were generated using the CRISPR/Cas9 system. CRISPR-mediated mutagenesis was done by the Genome Engineering and IPSC Center (GEiC) at Washington University. The CRISPR nucleases were validated to ensure that they cut the desired endogenous chromosomal target sites. All successful mutants were verified through deep sequencing. To generate mice with adipose-specific knockout of Prdm16, Pex16, or Acox1, floxed mice for each line were crossed with adiponectin-Cre transgenic mice (18). To generate BAT-specific Pex16-KO mice, Pex16loxP/loxP mice were crossed with Ucp1-Cre mice (59). For each line, respective floxed mice without Cre were used as control. Mice were housed at room temperature (22°C) and fed Picolab Rodent Diet 20 control chow or Harlan Teklad TD 88137 HFD (42% calories from fat), as indicated. For thermoneutrality experiments, the mice were housed at 30°C. The AG diet was generated by incorporating 1 g/kg each of 1-O-hexadecyl-rac-glycerol (Chem-Impex International Inc.) and 1-O-octadecyl-rac-glycerol (Bachem) into Picolab Rodent Diet 20. For cold tolerance studies, mice were individually housed at 4°C, and rectal temperature was measured using an Exttech thermocouple thermometer. For other analysis related to cold exposure, mice were housed together at 4°C for 48 hours, unless otherwise noted.

**Cell lines.** Human embryonic kidney 293T (HEK293T) cells and COS-7 cells were maintained in DMEM supplemented with 10% FBS. Stromal vascular fractions from mouse iWAT and BAT were isolated, immortalized, and differentiated into adipocytes as previously reported (46). Briefly, confluent BAT SVF cells were treated with DMEM/F12 supplemented with 0.5 μM isobutylmethylxanthine, 5 μM dexamethasone, 125 μM indomethacin, 1 μM rosiglitazone, 1 nM T3, and 0.02 μM insulin. After 2 days, the cells were switched to medium supplemented only with 1 nM T3 and 0.02 μM insulin (maintenance medium), which was replaced every 2 days. iWAT SVF cells were differentiated into adipocytes as previously described (60).

**Antibodies.** Rabbit polyclonal antibodies against actin (1:3000; catalog A2066) and PMP70-Atto-488 (1:100; catalog P0090) as well as mouse monoclonal antibodies against FLAG (1:1000; catalog F1804) and PMP70 (1:2000; catalog SAB4200181) and mouse polyclonal antibody against Pex14 (1:1000; catalog SAB1409439) were from MilliporeSigma. Rabbit polyclonal antibodies against Pex16 (1:1000; catalog 14816-1-AP), Acox1 (1:1000; catalog 10957-1-AP), and GNPAT (1:1000; catalog 14931-1-AP) were from Proteintech. Rabbit polyclonal anti-FAS antibody (1:5000; catalog ab22759) was purchased from Abcam. Anti-UCP1 rabbit antibody (1:1000; catalog UCP11-A) was purchased from Alpha Diagnostics. Mouse monoclonal antibodies against COXIV (1:1000; catalog 11967S) and Drp1 (1:1000; catalog 14647S) and a rabbit polyclonal antibody against Tomm22 (1:1000; catalog 42406S) were from Cell Signaling Technology. Anti-β-tubulin rabbit polyclonal (1:1000; SC-9104) and anti-AGPS mouse monoclonal (1:1000; catalog SC-374201) antibodies were from Santa Cruz Biotechnology Inc. Light chain–specific HRP-conjugated secondary antibodies (1:2500; catalog 211-032-171 and 115-035-174) were from Jackson ImmunoResearch Laboratories Inc.

**Plasmid constructs.** To construct the Pex16-eGFP reporter construct, a ~2 kb Pex16 promoter was amplified by PCR using liver genomic DNA from a WT C57 mouse and cloned into a pEGFP-N1 plasmid in place of the CMV promoter. To generate the Pex16-Luciferase reporter plasmid, the gene encoding firefly luciferase was amplified by PCR using the pPRE X3-TK-luc plasmid (Addgene) as template. The luciferase gene was then cloned into the Pex16-eGFP plasmid in place of eGFP using the restriction enzymes AgeI and NotI. To create the lentiviral Mito-roGFP construct, roGFP containing a mitochondrial localization sequence was amplified by PCR using a previously generated adenoviral Matrix-roGFP2 (Addgene plasmid 49437) construct as template (40). The resulting amplicon was cloned into a pLJM1-EGFP plasmid (Addgene plasmid 19319) in place of eGFP using restriction sites AgeI and EcoRI. The lentiviral plasmid pLenti-Myc-Flu4-mCherry was obtained from Addgene (plasmid 64049) and has been previously described (61).

**ChIP-qPCR assays.** ChIP studies were conducted using the SimpleChIP Enzymatic Chromatin IP Kit (Cell Signaling Technology) according to manufacturer’s instructions. Briefly, BAT SVF cells stably expressing FLAG-tagged PRM16 were fixed with 1% formaldehyde for 15 minutes. Nuclei were harvested and chromatin was digested by micrococcal nuclease before being lysed on ice by 3 sets of 10-second pulses from a Sonics VCV 500 probe sonicator at 30% amplitude. Chromatin was clarified by centrifugation before being incubated with FLAG M2 antibodies at 4°C overnight. ChIP-Grade Protein G agarose beads were incubated for 4 hours, spun, and washed. Crosslinks were reversed, and DNA was purified by spin column. DNA was quantified by qPCR using PowerUp SYBR Green Master Mix (Thermo Fisher Scientific) in triplicate, and data are shown as percentage of input. Primer sequences used in qPCR are provided in Supplemental Table 1.

**Indirect calorimetry.** To measure basal VO2, carbon dioxide production (VCO2), and respiratory exchange ratio (RER) in HFD-fed animals, a PhenoMaster (TSE Systems) metabolic cage system was used. Mice were acclimated to the system for 24 hours before measurements were taken. To measure NE-stimulated VO2 in mice, an Oxymax Eco System (Columbus Instruments) was used. The mice were acclimated to the system for 4 hours. The OCR was measured for 20 minutes prior to and 60 minutes after administering NE (1 mg/kg, i.p. injection).

**Measurement of OCR in cultured adipocytes.** OCR in control and Pex16-knockdown BAT SVF cells was measured using an XF24 Extracellular Flux Analyzer with a FluxPak (Seahorse Bioscience). The cells were seeded and grown to confluence on XF24 cell culture microplates before treatment with differentiation media, as previously described (46). On day 2, the cells were treated with scrambled or Pex16 shRNA lentivirus in the maintenance media. After 72 hours of treatment, the viral media were removed and replaced with fresh maintenance media. On day 8 of differentiation, OCR was measured at 3-minute intervals at baseline and after the addition of 2 μM NE, 3 μM oligomycin, 2 μM antimycin A, and 1 μM rotenone.

**High-resolution respirometry.** Mitochondrial respiration in BAT and iWAT from Pex16-AKO and control mice was measured using a modification of a previously reported method (62). After excision, adipose samples were immersed in cold BIOPs (10 mM EGTA, 50 mM MES, 0.5 mM DTT, 6.56 mM MgCl2, 5.77 mM ATP, 20 mM imidazole, and 15 mM phosphocreatine, pH 7.1) until tissue preparation. After all samples were collected, tissue was blotted dry, weighed, and then minced into approximately 2-mg pieces with...
scissors. Minced samples were placed in prewarmed OROBOROS chambers with mitochondrial respiration solution MIR05 (0.5 mM EGTA, 3 mM MgCl₂, 60 mM k-lactobionate, 20 mM taurin, 10 mM KH₂PO₄, 20 mM HEPES, 110 mM sucrose, and 1 g/l BSA, pH 7.1). Digitonin (2 μM) was added to each chamber to permeabilize the samples. Oxygen was added to each chamber to ensure oxygen availability within the tissue pieces. Oxygen levels were maintained above 250 pmol during the assay. To measure O₂ flux, the following substrates were added sequentially: octanoyl carnitine (1.5 mM), pyruvate (5 mM), glutamate (10 mM) and malate (2 mM), ADP (20 mM), and succinate (20 mM), followed by 3 pulses of 0.5 μM FCCP. A period of stabilization followed the addition of each substrate, and the oxygen flux per mass was recorded using DatLab 6.1 software (OROBOROS Instruments).

**TEM.** For TEM analysis of BAT, control and Pex16-AKO mice were sacrificed and perfused with warm Ringer’s solution for 2 minutes at 37°C, followed by 2% paraformaldehyde plus 2.5% glutaraldehyde, in 0.09 M cacodylate buffer, pH 7.2, containing 5% sucrose and 0.025% CaCl₂ at 37°C for 5 minutes. Peroxisomes were visualized by staining with DAB as previously described (63), and images were acquired using a JEOL JEM-1400Plus Transmission Electron Microscope.

**Mitochondrial morphology assay.** BAT SVF cells stably expressing Mito-roGFP were seeded in 24-well plates with high performance #1.5 cover glass bottoms (Cellvis P24-1.5H-N), grown to confluence and then treated with brown adipocyte differentiation cocktail as previously described (46). Four days after the initiation of differentiation, the cells were infected with scrambled, Pex16, or GNPAT shRNA lentivirus in the differentiation medium. After 24 hours, the viral medium was removed and fresh differentiation medium was added. On day 9 of differentiation, the medium was removed and the cells were washed with prewarmed PBS before addition of phenol red-free DMEM containing a 10% solution of BackDrop Green reagent. Mitochondrial morphology was quantified by visual inspection, and cells were divided into 3 groups, exhibiting fragmented, fused, or intermediate (partially fragmented) mitochondria, as previously described (23).

**Oxidation assays.** BAT, muscle, or liver from control and Pex16-AKO mice was homogenized in a buffer containing 250 mM sucrose, 1 mM EDTA, 10 mM Tris-HCl, and 2 mM ATP in a glass homogenization tube with a motor-driven Teflon pestle at 4°C. Following homogenization, tissue homogenates were transferred to 1.5-mL microcentrifuge tubes and centrifuged at 10,000 g for 10 minutes at 4°C. Supernatant was obtained, and protein concentration was measured. Homogenate (40 μL) was added to a 48-well plate with adjacent wells connected by a fabricated groove. 200 μL of 1 M NaOH was added to wells adjacent to sample wells to trap CO₂ generated by the oxidation reaction. A 160-μL aliquot of reaction mixture was added to sample wells and then sealed with parafilm covered by a rubber gasket. Final concentration of reagents in the mixture were 100 mM sucrose, 10 mM Tris-HCl, 5 mM KH₂PO₄, 100 mM KCl, 1 mM MgCl₂, 1 mM L-carnitine, 0.1 mM malate, 2 mM ATP, 0.05 mM coenzyme A, 1 mM DTT, and either 0.1 mM palmitate ([1-¹⁴C]palmitate, 0.5 μCi/ml) in 0.5% BSA, 0.1 mM sodium pyruvate ([2-¹⁴C]sodium pyruvate, 0.5 μCi/ml) in 0.5% BSA, or 0.025 mM lignoceric acid ([1-¹⁴C]lignoceric acid, 0.5 μCi/ml) in 25 mg/ml α-cyclodextrin. After 60 minutes (palmitate and pyruvate) or 4 hours (lignoceric acid) of incubation at 37°C, 100 μL of 70% perchloric acid was added. On day 9 of differentiation, the medium was removed and fresh differentiation medium was added, followed by 3 pulses of 0.5 μM FCCP. A period of stabilization followed the addition of each substrate, and the oxygen flux per mass was recorded using DatLab 6.1 software (OROBOROS Instruments).

**Statistics.** Results with error bars express mean ± SEM. Comparisons between 2 groups were performed using 2-tailed Student’s t test. To assess statistical significance in the survival curves, Mantel-Cox (log-rank) test was used. ANOVA was used for more than 2 groups. A P value less than 0.05 was considered significant. Statistical significance is represented as follows: *P < 0.05, **P < 0.01, ***P < 0.001.

**Study approval.** All animal experiments were performed in accordance with procedures approved by the Institutional Animal Care and Use Committee at Washington University School of Medicine.

**Author contributions**
HP and AH conceived hypotheses, designed and conducted experiments, and performed data analyses. JMJ, JMD, and TAP conducted experiments and performed data analysis. MT, YC, and XZ performed experiments. FFH performed mass spectrometry analyses, assigned structures of lipid molecules, and interpreted data. KA and BR designed experiments. IJL conceived the study, designed experiments, performed data analysis, and wrote the manuscript.
