Small Bowel Obstruction Secondary to Wild Banana Seed Ingestion

Divya K. Natarajan,¹ Phonexay Homthavong,^{2,3} and Indi Trehan^{1,2*}

¹Department of Pediatrics, Washington University in St. Louis, St. Louis, Missouri; ²Lao Friends Hospital for Children, Luang Prabang, Lao PDR; ³Luang Prabang Provincial Hospital, Luang Prabang, Lao PDR

A previously healthy 13-year-old boy from a rural village in northern Laos presented with progressive abdominal pain, constipation, emesis, and marked abdominal distention. Radiographs showed a small bowel obstruction which did not resolve with conservative management (Figure 1). At laparotomy, a bezoar was identified as the cause of his bowel obstruction (Figure 2). Resection of the mass identified a phytobezoar of banana seeds (Figure 3). The patient tolerated surgery well and had an unremarkable postoperative course.

Further history obtained postoperatively revealed that before presentation, the patient was hungry and foraging for food for several days as his family was without means and reliable access to food. He chanced on a wild banana tree and indulged in its fruits.

The offending fruit, *Musa balbisiana*, is a wild banana species native to Southeast Asia, spanning from India to Papua New Guinea (Figure 4). Ingestion of the fruit seeds is known to cause intestinal complications, including constipation, appendicitis, and small bowel obstruction, most commonly in rural, impoverished populations because of limited access to safe nutrition.^{1–4} Despite local wisdom to avoid these dangerous fruits and multiple reports of wild

banana ingestion–related bowel obstruction, cases like this demonstrate the impact that food insecurity and starvation can have on impoverished populations.
