Provision of No-Cost, Long-Acting Contraception and Teenage Pregnancy

Gina M. Secura, Ph.D., M.P.H., Tessa Madden, M.D., M.P.H., Colleen McNicholas, D.O., Jennifer Mullersman, B.S.N., Christina M. Buckel, M.S.W., Qiuhong Zhao, M.S., and Jeffrey F. Peipert, M.D., Ph.D.

BACKGROUND
The rate of teenage pregnancy in the United States is higher than in other developed nations. Teenage births result in substantial costs, including public assistance, health care costs, and income losses due to lower educational attainment and reduced earning potential.

METHODS
The Contraceptive CHOICE Project was a large prospective cohort study designed to promote the use of long-acting, reversible contraceptive (LARC) methods to reduce unintended pregnancy in the St. Louis region. Participants were educated about reversible contraception, with an emphasis on the benefits of LARC methods, were provided with their choice of reversible contraception at no cost, and were followed for 2 to 3 years. We analyzed pregnancy, birth, and induced-abortion rates among teenage girls and women 15 to 19 years of age in this cohort and compared them with those observed nationally among U.S. teens in the same age group.

RESULTS
Of the 1404 teenage girls and women enrolled in CHOICE, 72% chose an intrauterine device or implant (LARC methods); the remaining 28% chose another method. During the 2008–2013 period, the mean annual rates of pregnancy, birth, and abortion among CHOICE participants were 34.0, 19.4, and 9.7 per 1000 teens, respectively. In comparison, rates of pregnancy, birth, and abortion among sexually experienced U.S. teens in 2008 were 158.5, 94.0, and 41.5 per 1000, respectively.

CONCLUSIONS
Teenage girls and women who were provided contraception at no cost and educated about reversible contraception and the benefits of LARC methods had rates of pregnancy, birth, and abortion that were much lower than the national rates for sexually experienced teens. (Funded by the Susan Thompson Buffett Foundation and others.)
ALTHOUGH IT HAS DECLINED SUBSTANTIALLY over the past two decades, the pregnancy rate among girls and women 15 to 19 years of age remains a stubborn public health problem. Each year, more than 600,000 teens become pregnant, and 3 in 10 teens will become pregnant before they reach 20 years of age.1-2 Rates are higher among black and Hispanic teens, with 4 in 10 becoming pregnant by 20 years of age, as compared with 2 in 10 white teens.2-4 In addition to the negative health and social consequences borne by teenage mothers and their children, the national financial burden is substantial. In 2010, births involving teenage mothers cost the United States nearly $10 billion in increased public assistance and health care and in income lost as a result of lower educational attainment and reduced earnings among children born to teenage mothers.5

The President’s Teen Pregnancy Prevention Initiative was launched in 2010 to address the high teenage pregnancy rate by replicating evidence-based models and innovative strategies.6 Teenage pregnancy has also been designated by the Centers for Disease Control and Prevention (CDC) as one of the six Winnable Battles because of the magnitude of the problem and the belief that it can be addressed by strategies that are known to be effective.7 The Winnable Battle target is to reduce the teenage birth rate by 20%, from 37.9 births per 1000 teens in 2009 to 30.3 per 1000 by 2015.

Long-acting, reversible contraceptive (LARC) methods, which include intrauterine devices (IUDs) and implants, have been shown to be acceptable to teens and young women, with higher continuation rates than shorter-acting methods.8,9 LARC methods reduce the likelihood of pregnancy and of repeat pregnancy among adolescents,10,11 yet less than 5% of U.S. teens report using LARC methods.12

Lack of information about effective contraception, limited access, and cost remain barriers to the use of LARC methods by teens.13-15 It is unclear whether removal of these barriers can reduce unintended pregnancy and birth rates among high-risk, sexually active teens. We assessed pregnancy, birth, and abortion rates in a cohort of teens among whom these three barriers to highly effective reversible contraception were removed, and we compared these rates with rates observed nationally among all teens in the United States.

STUDY ENROLLMENT

The Contraceptive CHOICE Project was a prospective cohort study involving 9256 St. Louis area girls and women 14 to 45 years of age, in which the use of LARC methods was promoted to reduce unintended pregnancy.16 Participants were recruited through referral from medical providers, word of mouth, and study flyers. The Washington University School of Medicine in St. Louis Human Research Protection Office approved the study protocol before recruitment began, and all participants provided written informed consent. Participants 14 to 17 years of age provided written assent, and a parent or guardian provided written consent. Minors could enroll under a waiver of parental consent if they did not know the whereabouts of their parents or guardians or if they did not want their parents or guardians to know that they were seeking contraception. We enrolled four minors using the waiver.

Women and adolescent girls were eligible to participate in CHOICE if they were English-speaking or Spanish-speaking, resided in the St. Louis region or sought contraceptive services in selected community clinics, had no desire for pregnancy for at least 12 months, were sexually active or planning to be sexually active with a male partner during the next 6 months, and were not using a contraceptive method or were willing to switch to a new, reversible contraceptive method. Women and adolescent girls were ineligible if they had undergone a hysterectomy or sterilization procedure.

STUDY DESIGN

CHOICE provided standardized contraceptive counseling to study participants regarding commonly used reversible contraceptive methods.17 Methods were presented in order from most to least effective, and the potential side effects, risks, and benefits of each method were reviewed. Participants were provided with their chosen method at their enrollment session in accordance with evidence-based clinical guidelines.18,19 If medical contraindications did not allow for same-day insertion of a LARC device (e.g., if pregnancy could not be ruled out definitively or if the participant had active cervicitis), participants received a shorter-acting method, such as oral contraceptive pills or depot medroxyprogesterone acetate (DMPA) injection, until their chosen meth-
od could be initiated. During the enrollment session, study staff performed a baseline interview, and participants were screened for sexually transmitted infections.

Participants were followed for 2 to 3 years, depending on their enrollment date. Telephone interviews were administered by study staff at 3 and 6 months and every 6 months thereafter. Participants received a $10 gift card after every completed follow-up survey. During the baseline and follow-up surveys, we collected detailed information regarding demographic characteristics and reproductive history, including contraceptive method use and satisfaction, sexual behavior, and pregnancy.

This analysis involves the 1404 adolescents who enrolled in CHOICE between 14 and 19 years of age, from 2007 through 2011; 716 teens were followed for 3 years, and 688 teens were followed for 2 years. At each follow-up survey, we asked participants if they had had a pregnancy. Participants who contacted study staff outside a scheduled survey or came to the clinic with concerns about possible pregnancy completed a urine pregnancy test. We recorded all pregnancies in a pregnancy log and documented the contraceptive method used at the time of conception. If the outcome of the pregnancy was known at the time of the survey (e.g., birth, miscarriage, or abortion), it was documented in the pregnancy log. If a participant was currently pregnant, we subsequently contacted her to record the pregnancy outcome.

STUDY OUTCOMES

The primary outcomes of the study were the rates of pregnancy, live birth, and induced abortion; teen-years of use of contraceptive methods; and failure rates of contraceptive methods included data collected when members of the cohort were 15 to 19 years of age.

STATISTICAL ANALYSIS

We used frequencies, percentages, medians, and ranges to describe the demographic and reproductive characteristics of the participants at the time of study enrollment. A chi-square test was performed for categorical data, and a Wilcoxon two-sample test was performed for continuous data that was not normally distributed.

For this analysis, we calculated annual means and 95% confidence intervals for rates of pregnancy, live birth, and induced abortion from 2008 through 2013, because the number of pregnancies and pregnancy outcomes that occurred among teenage CHOICE participants each year was small. Each rate represents the total number of events (i.e., pregnancy, birth, or abortion) that occurred among the participants divided by the total amount of time contributed from 2008 through 2013. For a pregnancy to be considered in the analysis, the outcome of the pregnancy (i.e., birth or abortion, for the purposes of this study) had to occur before 20 years of age. This is the same approach used by the National Center for Health Statistics in calculating U.S. rates.1 We calculated the time contributed by each participant during which she was not pregnant. If at the last survey the participant reported she had not been pregnant since the previous contact, we subtracted 6 weeks of contributed time to account for the possibility of an early-stage and unknown pregnancy. For a participant who had a pregnancy, we subtracted the total time she was pregnant plus 1 month if she delivered, to account for postpartum infecundity. For participants who were lost to follow-up, the last date of contact was the cutoff point for outcomes and contributed time. All analyses were performed with the use of Stata software, version 11 (StataCorp).

RESULTS

CHARACTERISTICS OF THE PARTICIPANTS

Table 1 gives the baseline demographic and reproductive characteristics of the 1404 teenage participants, stratified by age group at enrollment (14 to 17 years vs. 18 to 19 years). Nearly 500 minors 14 to 17 years of age were enrolled in the
Long-Acting Contraception and Teenage Pregnancy

study. Nearly half the participants reported a previous unintended pregnancy, and 18% had a history of abortion. As compared with younger teens, those who were 18 to 19 years of age reported more lifetime male sex partners and greater parity and had a higher frequency of previous sexually transmitted infections. The majority of teens in both age groups chose LARC methods, but teens 14 to 17 years of age were more likely than older teens to do so (77.5% vs. 68.4%, P<0.001). The implant was the most common contraceptive choice for participants 14 to 17 years of age, whereas an IUD was most commonly chosen by older teens (Table 1).

Pregnancy, Birth, and Abortion Rates

The 12-month, 24-month, and 36-month follow-up rates among CHOICE participants were 92%, 82%, and 75%, respectively. During 1738 teen-years of follow-up between 2008 and 2013, teens in the CHOICE cohort reported 56 pregnancies, 32 births, 16 induced abortions, 7 miscarriages,

* P values are for the comparison between the age groups (14 to 17 vs. 18 to 19 years of age).
†† Race was self-reported.
‡‡ Participants were classified as having low socioeconomic status if they reported current receipt of food stamps; vouchers from the Special Supplemental Nutrition Program for Women, Infants, and Children; other welfare benefits; unemployment benefits; or difficulty in paying for transportation, housing, health or medical care, or food.
§§ Data are based on a self-reported history of chlamydia infection, gonorrhea, or trichomoniasis.
¶¶ DMPA denotes depot medroxyprogesterone acetate, and IUD intrauterine device.
and 1 stillbirth. Reported methods used at the time of conception included the levonorgestrel IUD (2 participants), DMPA injection (1), oral contraceptive pills (13), the ring (4), the patch (2), condoms (9), and no method (25). The teen-years of use and failure rates of contraceptive methods among the participants using these methods were as follows: 394.2 teen-years and 5.1 failures per 1000 teen-years for the levonorgestrel IUD, 193.8 teen-years and 5.2 failures per 1000 teen-years for DMPA injection, 229.0 teen-years and 56.8 failures per 1000 teen-years for oral contraceptive pills, 77.2 teen-years and 51.8 failures per 1000 teen-years for the contraceptive ring, and 32.9 teen-years and 60.8 failures per 1000 teen-years for the contraceptive patch. No pregnancies occurred with the copper IUD (57.3 teen-years) or the etonogestrel subdermal implant (633.3 teen-years).

Table 2 gives the overall rates of pregnancy, live birth, and induced abortion in the CHOICE teenage cohort; respective rates for teens in the United States in 2010 are provided for comparison. The mean annual rates were 34.0 per 1000 teens (95% confidence interval [CI], 25.7 to 44.1), 19.4 per 1000 (95% CI, 13.3 to 27.4), and 9.7 per 1000 (95% CI, 5.6 to 15.8), respectively. The corresponding 2010 rates among U.S. teens nationally were 57.4, 34.4, and 14.7 per 1000.

Among teenage girls and women enrolled in CHOICE, 97% were sexually experienced at baseline, and 99% were sexually experienced by 12 months of follow-up. Thus, Table 2 also presents a comparison of the mean annual rates in CHOICE as compared with 2008 U.S. rates representing only sexually experienced teens. The pregnancy, birth, and abortion rates per 1000 sexually experienced U.S. teens in 2008 were 158.5, 94.0, and 41.5, respectively.

Figure 1 shows the pregnancy, birth, and abortion rates among CHOICE participants, as compared with the 2010 rates among all U.S. teens. The rates were stratified according to age group and race. For all three outcomes within each stratum, the rates among CHOICE participants were lower than the U.S. rates. The difference between rates in CHOICE and national rates was greater for those 18 to 19 years of age and among black teens. Figure 2 shows the pregnancy rates among CHOICE teens, as compared with sexually experienced U.S. teens, according to age group and race. For both age groups and both races, the CHOICE rates were substantially lower than the national rates.

* Data are U.S. rates for the year 2010.† Data are U.S. rates for the year 2008.‡ Data are the mean annual rates for the years 2008 through 2013. CI denotes confidence interval.

We found that pregnancy, birth, and abortion rates were low among teenage girls and women enrolled in a project that removed financial and access barriers to contraception and informed them about the particular efficacy of LARC methods. The observed rates of pregnancy, birth, and abortion were substantially lower than national rates among all U.S. teens, particularly when compared with sexually experienced U.S. teens. Stratification according to factors known to be associated with sexual behavior and pregnancy risk (age and race)21 showed that this was true among both older teens (18 to 19 years of age) and younger teens, as well as among both white and black teens.

The CDC Winnable Battle 2015 goal for teenage births is 30.3 per 1000 teens. The mean annual teenage birth rate in our cohort was 19.4 per 1000 teens, 36% lower than the 2015 goal. Our teenage pregnancy and birth rates reflect teens using highly effective contraception, with a high rate of LARC use in this cohort (i.e., 72% overall among teens). Although the rate of LARC use among teens 15 to 19 years of age in the United States has increased from less than 1% in 2002 to almost 5% in 2009, our study suggests that it is possible to achieve a much greater rate of use.12 Furthermore, teens in our cohort continued to use LARC methods longer than short-
long-acting contraception and teenage pregnancy

... methods such as the oral contraceptive pill and DMPA injection; two thirds of teens in CHOICE were still using their LARC method at 24 months of follow-up, as compared with only one third of teens using a non-LARC method.8

The limitations of our study must be considered. First, information about pregnancy was self-reported by participants, and thus it is possible that the number of teenage pregnancies was underestimated in the CHOICE cohort. The U.S. pregnancy statistics rely on a composite of birth data, the abortion surveillance system, and self-reporting to estimate pregnancy rates. Second, teens were surveyed on a regular basis regarding their contraceptive method use, which may have influenced adherence to their contraceptive method. Third, the generalizability of our results is uncertain. Teens in CHOICE received standardized contraceptive counseling during which methods were presented in order from most to least effective. This counseling approach may differ from the usual counseling that teens receive in the United States but could certainly be applied in routine practice. Fourth, the enrollment of minors in CHOICE required parental consent. Most teens can access confidential contraceptive services without parental notification or consent, regardless of age. Minors who enrolled in CHOICE with the consent of their parent or guardian may represent a group of teens at lower risk for contraceptive nonuse and pregnancy.22 However, as compared with teens nationally, the teens enrolled in CHOICE are at greater risk for unintended pregnancy; 60% of the participants are black (vs. 16% of female teens 15 to 19 years of age in the United States),21 and almost all had sexual intercourse at the time of enrollment, with nearly three quarters reporting sexual intercourse in the previous 30 days (vs. national frequencies of 43% and one quarter, respectively).21

A final limitation is that we compared a mean annual rate for the period from 2008 through 2013 with 2010 national rates. From 2008 to 2010, the pregnancy rate declined by 15% among all teens in the United States. The most recent birth data (2012) indicate that the birth rate among teens 15 to 19 years of age dropped to 29.4 per 1000, the lowest rate ever reported for the United States.24 (Data on national pregnancy and abortion rates are not yet available beyond 2010.) Even with this continued decline, the reductions observed in CHOICE are substantial and of public health importance.

In summary, we found that in a cohort of teenage girls and women for whom barriers to con-
large percentage opted to use LARC methods. The rates of pregnancy, birth, and abortion in our cohort were below both the most recent corresponding national rates and the CDC Winnable Battle 2015 goal.
